---

7 We consider the NP-hard problem of finding a smallest decision tree which represents a given partially  
8 defined Boolean formula. We establish fixed-parameter tractability of the problem with respect to  
9 the NLC-width of the instance. We formulate a dynamic programming procedure which utilizes  
10 the NLC-decomposition of the instance. For this to work, we establish a succinct representation  
11 of partial solutions, so that the space and time requirements of each dynamic programming step  
12 remain bounded in terms of the NLC-width.

## 1 Introduction

Decision trees have proved to be extremely useful tools for the describing, classifying, generalizing data [18, 22, 25]. In this paper, we consider decision trees for *classification instances (CIs)*, consisting of a finite set  $E$  of *examples* (also called *feature vectors*) over a finite set  $F$  of *features*. Each example  $e \in E$  is a function  $e : F \rightarrow \{0, 1\}$  which determines whether the feature  $f$  is true or false for  $e$ . Moreover,  $E$  is given as a partition  $E^+ \uplus E^-$  into positive and negative examples. For instance, examples could represent medical patients and features diagnostic tests; a patient is positive or negative corresponding to whether they have been diagnosed with a certain disease or not. CIs are also called *partially* or *incompletely defined Boolean functions*, as we can consider the features as Boolean variables, and examples as truth assignments that evaluate to 0 (for positive examples) or 1 (for negative examples). CIs have been studied as a key concept for the logical analysis of data and in switching theory [4, 6, 5, 7, 8, 17, 20].

Because of their simplicity, decision trees are particularly attractive for providing interpretable models of the underlying CI, an aspect whose importance has been strongly emphasized over the recent years [10, 12, 15, 19, 21]. In this context, one prefers *small trees*, as they are easier to interpret and require fewer tests to make a classification. Small trees are also preferred in view of the parsimony principle (Occam's Razor) since small trees are expected to generalize better to new data [2]. However, finding a small decision tree, as formulated in the following decision problem, is NP-complete [16].

MINIMUM DECISION TREE SIZE (DTS): given a CI  $E = E^+ \uplus E^-$  and an integer  $s$ , is there a decision tree with at most  $s$  nodes for  $E$ ?

Given this complexity barrier, we propose a fixed-parameter algorithm for the problem, which exploits the input CI's hidden structure. The *incidence graph* of a CI is the bipartite graph  $G_I(E)$  whose vertices are the examples on one side and the features on the other, where an example  $e$  is adjacent with a feature  $f$  if and only if  $e(f) = 1$ . Figure 1 shows a CI and a smallest decision tree for it, as well as the incidence graph.

Key to our algorithm are new notions for succinctly representing decision trees that correspond to subtrees of the incidence graph's tree decomposition. Based on that, we can carry out a dynamic programming (DP) procedure along the tree decomposition.

While the DP approach using treewidth is quite well understood and can often be quite easily designed for problems on graphs (or more generally problems whose solutions can be represented in terms of the graph for which the tree decomposition is given), the same DP approach can become rather involved if applied to problems whose solutions have no or only minor resemblance to the graph for which one is given a tree decomposition. Probably the most prominent example for this is the celebrated result by Bodlaender [3], where he uses a

■ **Figure 1** A CI  $E = E^+ \uplus E^-$  with six examples and four features (left), a decision tree with 5 nodes that classifies  $E$  (middle), the incidence graph  $G_I(E)$  (right).

DP approach on an approximate tree decomposition to compute the exact treewidth of a graph; here, the solutions are tree decompositions, which are complex structures that cannot easily be represented in terms of the graph. Other prominent examples include a DP approach to compute the exact treedepth [26] or clique-width [14] using an optimal tree decomposition. We face a similar problem, since solutions in our case are decision trees that do not bear any resemblance to the incidence graph for which we are given the tree decomposition. The main obstacle to overcome, therefore, is the design of the DP-records for our DP algorithm. That is, a record for a node  $b$  in a tree decomposition for the incidence graph of  $E$  needs to provide a compact representation of partial solutions, i.e. partial solutions in the sense that they represent the part of the solution for the whole instance  $E$  that corresponds to the sub-instance induced by all features and examples contained in the bags in the subtree of the tree decomposition rooted at the current node  $b$ . We overcome this obstacle in Section 3, where we also provide intuitive descriptions and motivation for the definition of the records (Subsection 3.1).

## 2 Preliminaries

### 2.1 Parameterized Complexity

We give some basic definitions of Parameterized Complexity and refer for a more in-depth treatment to other sources [9, 13]. Parameterized complexity considers problems in a two-dimensional setting, where a problem instance is a pair  $(I, k)$ , where  $I$  is the main part and  $k$  is the parameter. A parameterized problem is *fixed-parameter tractable* if there exists a computable function  $f$  such that instances  $(I, k)$  can be solved in time  $f(k)|I|^{O(1)}$ .

### 2.2 Graphs and NLC-width

We will assume that the reader is familiar with basic graph theory (see, e.g. [11, 1]). We consider (vertex and edge labelled) undirected graphs. Let  $G = (V, E)$  be an undirected graph. We write  $V(G) = V$  and  $E(G) = E$  for the sets of vertices and edges of  $G$ , respectively. We denote an edge between  $u \in V$  and  $v \in V$  as  $\{u, v\}$ . For a set  $V' \subseteq V$  of vertices we let  $G[V']$  denote the graph induced by the vertices in  $V'$ , i.e.  $G[V']$  has vertex set  $V'$  and edge set  $E \cap \{\{u, v\} \mid u, v \in V'\}$  and we let  $G - V'$  denote the graph  $G[V \setminus V']$ . For a set  $E' \subseteq E$  of edges we let denote  $G - E'$  the graph with vertex set  $V$  and edge set  $E \setminus E'$ .

A  $k$ -graph is a pair  $(G, \lambda)$ , where  $G = (V, E)$  is an undirected graph and  $\lambda : V \rightarrow [k]$  is a *vertex label mapping* that labels every vertex  $v \in V$  with a label  $\lambda(v)$  from  $[k]$ . We call the  $k$ -graph consisting of exactly one vertex  $v$  (say, labeled by  $i$ ) an *initial  $k$ -graph* and denote it by  $i(v)$ .

Node label control-width (*NLC-width*) is a graph parameter, defined as follows [28]: Let  $k \in \mathbb{N}$  be a positive integer. An  $k$ -NLC-expression tree of a graph  $G = (V, E)$  is a subcubic tree  $B$ , where every node  $b$  of  $B$  is associated with a  $k$ -graph (denoted by  $(G_b, \lambda_b)$ ), such that:

1. Every leaf represents an initial  $k$ -graph  $i(v)$  with  $i \in [k]$  and  $v \in V$ .
2. Every non-leaf node  $b$  with one child  $c$  is a *relabeling node* and is associated with a relabeling function  $R_b : [k] \rightarrow [k]$ . Moreover,  $G_b$  is obtained from  $G_c$  after relabelling all vertices of  $G_c$  with label  $i$  to label  $R_b(i)$  for every  $i \in [k]$ .
3. Every non-leaf node  $b$  with two children, i.e., a left child  $l$  and a right child  $r$ , is a *join node* and is associated with a *join matrix*, i.e., a binary  $k \times k$  matrix  $M_b$ . Moreover,

- 96  $(G_b, \lambda_b)$  is obtained from the disjoint union of  $(G_l, \lambda_l)$  and  $(G_r, \lambda_r)$  after adding an edge  
 97 from all vertices labeled  $i$  in  $G_l$  to all vertices labeled  $j$  in  $G_r$  whenever  $M_b[i, j] = 1$ .  
 98 4.  $G$  is equal to the  $G_r$  for the root node  $r$  of  $B$ .

99 The NLC-width of a graph  $G$ , denoted by  $nlcw(G)$ , is the minimum  $k$  for which  $G$  has  
 100 a  $k$ -NLC-expression tree. A  $k$ -NLC-expression tree is *nice* if every relabelling node has a  
 101 relabelling function  $R : [k] \rightarrow [k]$  such that for some  $i, j \in [k]$ ,  $R(i) = j$  and  $R(\ell) = \ell$  for all  
 102  $\ell \in [k] \setminus \{i\}$ . Clearly, given a  $k$ -NLC-expression tree, a nice  $k$ -NLC-expression tree can be  
 103 found in polynomial time; simply replace every relabelling node (that relabels more than one  
 104 label at a time) by a sequence of relabelling nodes.

105 Let  $b$  be a node in a  $k$ -NLC-expression tree of a graph  $G$ . We denote by  $V_b$  the set of  
 106 vertices of  $G_b$ . By the definition of a  $k$ -NLC-expression tree, if  $u, v \in V_b$  have the same label  
 107 in  $(G_b, \lambda_b)$  and  $w \in V(G) \setminus V_b$ , then  $u$  is adjacent to  $w$  in  $G$  if and only if  $v$  is.

108 Computing the NLC-width of a graph is NP-hard [?]. However, it is sufficient to use the  
 109 algorithm of Seymour and Oum [?], which returns a  $c$ -expression for some  $c \leq 2^{3cw(G)+2} - 1$   
 110 in  $O(n^9 \log n)$  time, or the later improvements of Oum [24] and Hliněný and Oum [?] that  
 111 provide cubic-time algorithms which yield a  $c$ -expression for some  $c \leq 8^{cw(G)} - 1$  and  
 112  $c \leq 2^{cw(G)+1} - 1$ , respectively.

## 113 2.3 Classification Problems

114 An *example*  $e$  is a function  $e : \text{feat}(e) \rightarrow \{0, 1\}$  defined on a finite set  $\text{feat}(e)$  of *features*. For  
 115 a set  $E$  of examples, we put  $\text{feat}(E) = \bigcup_{e \in E} \text{feat}(e)$ . We say that two examples  $e_1, e_2$  *agree*  
 116 on a feature  $f$  if  $f \in \text{feat}(e_1)$ ,  $f \in \text{feat}(e_2)$  and  $e_1(f) = e_2(f)$ . If  $f \in \text{feat}(e_1)$ ,  $f \in \text{feat}(e_2)$   
 117 but  $e_1(f) \neq e_2(f)$ , we say that the examples *disagree on*  $f$ .

118 A *classification instance* (CI) (also called a *partially defined Boolean function* [17])  
 119  $E = E^+ \uplus E^-$  is the disjoint union of two sets of examples, where for all  $e_1, e_2 \in E$  we have  
 120  $\text{feat}(e_1) = \text{feat}(e_2)$ . The examples in  $E^+$  are said to be *positive*; the examples in  $E^-$  are  
 121 said to be *negative*. A set  $X$  of examples is *uniform* if  $X \subseteq E^+$  or  $X \subseteq E^-$ ; otherwise  $X$  is  
 122 *non-uniform*.

123 Given a CI  $E$ , a subset  $F \subseteq \text{feat}(E)$  is a *support set* of  $E$  if any two examples  $e_1 \in E^+$   
 124 and  $e_2 \in E^-$  disagree in at least one feature of  $F$ . Finding a smallest support set, denoted  
 125 by  $\text{MSS}(E)$ , for a classification instance  $E$  is an NP-hard task [17, Theorem 12.2].

126 We define the *incidence graph* of  $E$ , denoted by  $G_I(E)$ , as the bipartite graph with  
 127 partition  $(E, \text{feat}(E))$  having an edge between an example  $e \in E$  and a feature  $f \in \text{feat}(e)$  if  
 128  $f(e) = 1$ .

## 129 2.4 Decision Trees

130 A *decision tree* (DT) (or *classification tree*) is a rooted tree  $T$  with vertex set  $V(T)$  and arc  
 131 set  $A(T)$ , where each non-leaf node (called a *test*)  $v \in V(T)$  is labelled with a feature  $\text{feat}(v)$ ,  
 132 each non-leaf node  $v$  has exactly two out-going arcs, a *left arc* and a *right arc*, and each leaf  
 133 is either a *positive* or a *negative* leaf. We write  $\text{feat}(T) = \{v \in V(T) \mid \text{feat}(v)\}$ .

134 Consider a CI  $E$  and a decision tree  $T$  with  $\text{feat}(T) \subseteq \text{feat}(E)$ . For each node  $v$  of  $T$  we  
 135 define  $E_T(v)$  as the set of all examples  $e \in E$  such that for each left (right, respectively)  
 136 arc  $(u, v)$  on the unique path from the root of  $T$  to  $v$  we have  $e(\text{feat}(u)) = 0$  ( $e(\text{feat}(u)) = 1$ ,  
 137 respectively).  $T$  *correctly classifies* an example  $e \in E$  if  $e$  is a positive (negative) example  
 138 and  $e \in E_T(v)$  for a positive (negative) leaf. We say that  $T$  *classifies*  $E$  (or simply that  $T$  is  
 139 a DT for  $E$ ) if  $T$  correctly classifies every example  $e \in E$ . See Figure 1 for an illustration of  
 140 a CI, its incidence graph, and a DT that classifies  $E$ .

141 The size of  $T$  is its number of nodes, i.e.  $|V(T)|$ . We consider the following problem.

MINIMUM DECISION TREE SIZE (DTS)

142 Input: A classification instance  $E$  and an integer  $s$ .  
 Question: Is there a decision tree of size at most  $s$  for  $E$ ?

143 We now give some simple auxiliary lemmas that are required by our algorithm.

144 ► **Lemma 1.** *Let  $A$  be a set of features of size  $a$ . Then the number of DTs of size at most  $s$*   
 145 *that use only features in  $A$  is at most  $a^{2s+1}$  and those can be enumerated in  $\mathcal{O}(a^{2s+1})$  time.*

146 **Proof.** We start by counting the number of trees  $T$  with  $n$  nodes that can potentially underlie  
 147 a DT with  $n$  nodes. Note that there is one-to-one correspondence between trees  $T$  that  
 148 underlie a DT with  $n$  nodes and unlabelled rooted ordered binary trees with  $n$  nodes (where  
 149 ordered refers to an ordering of the at most 2 child nodes). Since it is known that the number  
 150 of unlabelled rooted ordered binary trees with  $n$  nodes is equal to the  $n$ -th Catalan number  
 151  $C_n$  and that those trees can be enumerated in  $\mathcal{O}(C_n)$  time [27], we already obtain that we  
 152 can enumerate all of the at most  $C_n$  possible trees  $T$  underlying a DT of size  $n$  in  $\mathcal{O}(C_n)$   
 153 time. Therefore, there are at most  $sC_s$  possible trees of size at most  $s$  that can underlie a  
 154 DT with at most  $s$  nodes and those can be enumerated in  $\mathcal{O}(sC_s)$  time. It now remains  
 155 to bound the number of possible feature assignments  $\text{feat}(f)$  for these trees as well as the  
 156 number of possibilities for the leaf nodes that can be either labelled positive or negative.  
 157 Since we can assume that  $a \geq 2$ , we obtain that the number of possible feature assignments  
 158 (and labellings of leaf-nodes) of a tree  $T$  with  $n$  nodes is at most  $a^n$ . Taking everything  
 159 together, we obtain that there are at most  $sC_s a^s \leq s4^s a^s \leq a^{2s+1}$  many DTs of size at most  
 160  $s$  using only features in  $A$  and those can be enumerated in  $\mathcal{O}(a^{2s+1})$  time. ◀

161 ► **Lemma 2.** *Let  $A$  be a set of features of size  $a$ . There are at most  $a^{2^{a+1}+3}$  inclusion-wise*  
 162 *minimal DTs using only features in  $A$  and these can be enumerated in  $\mathcal{O}(a^{2^{a+1}+3})$  time.*

163 **Proof.** Note that an inclusion-wise minimal DT  $T$  that uses only features in  $A$  has at most  
 164  $2^a + 1$  nodes; this is because every feature appears at most once on every path  $T$ . Therefore, we  
 165 obtain from Lemma 1 that the number of choices for  $T$  is at most  $a^{2(2^a+1)+1} = a^{2^{a+1}+3}$ . ◀

166 ► **Lemma 3.** *Let  $E$  be a CI. Then one can decide whether  $E$  has a DT and if so output a*  
 167 *DT of minimum size for  $E$  in time  $\mathcal{O}((2^{|E|})^{4^{|E|-1}})$ .*

168 **Proof.** Note first that  $|\text{feat}(E)| \leq 2^{|E|}$  since we can assume that  $E$  does not contain two  
 169 equivalent features. Moreover,  $E$  has a DT if and only if  $\text{feat}(E)$  is a support set, which can be  
 170 checked in time  $\mathcal{O}(|E|^2 |\text{feat}(E)|)$  by checking, for every pair of positive and negative examples  
 171 in  $E$ , whether there is a feature that distinguishes them. If this is not the case, we output **NO**,  
 172 so assume that  $E$  has a DT. Note that any inclusion-wise minimal DT for  $E$  has at most  $|E|$   
 173 leaves and therefore size at most  $2|E| - 1$ . We can therefore employ Lemma 1 to enumerate  
 174 all inclusion-wise minimal potential DTs for  $E$  in time  $\mathcal{O}((2^{|E|})^{2(2|E|-1)+1}) \in \mathcal{O}((2^{|E|})^{4^{|E|-1}})$ .  
 175 For every such tree we then check whether it is indeed a DT for  $E$  and return a DT for  $E$  of  
 176 minimum size found during this process. ◀

### 177 **3 An FPT-Algorithm for NLC-width**

178 In this section, we present our main result, i.e. we will show that DTS is fixed-parameter  
 179 tractable parameterized by NLC-width.

180 ► **Theorem 4.** *Let  $E$  be a CI, let  $B$  be an NLC-decomposition of width  $\omega$  for  $G_I(E)$ , and*  
 181 *let  $s$  be an integer. Then, deciding whether  $E$  has a DT of size at most  $s$  is fixed-parameter*  
 182 *tractable parameterized by  $\omega$ .*

183 ► **Corollary 5.** *DTS is fixed-parameter tractable parameterized by NLC-width.*

todo: Due to  
proposition ...

184 In principle, we will use a dynamic programming algorithm along the NLC-decomposition  
 185  $(B, \chi)$  of  $G_I(E)$  that computes a set of records for every node  $b$  of  $B$  in a bottom-up manner.  
 186 Each record will represent an equivalence class of solutions (DTs) for the whole instance  
 187 restricted to the examples and features contained in the current subtree rooted in  $b$ , i.e.  
 188 the examples and features contained in  $\chi(b)$ . Before we continue with the formal notions  
 189 and definitions required to define the records, we want to illustrate the main ideas and  
 190 motivations. In what follows let  $B$  be an NLC-decomposition of  $G_I(E)$  of width  $k$ . For  
 191  $b \in V(B)$ , we write  $\text{feat}(b)$  and  $\text{exam}(b)$  for the sets  $\chi(b) \cap \text{feat}(E)$  and  $\chi(b) \cap E$ , respectively.

### 192 3.1 Description of the Main Ideas Behind the Algorithm

193 Consider a node  $b$  of  $B$ . To simplify the presentation, we will sometime refer to the features  
 194 and examples in  $\chi(B_b) \setminus \chi(b)$  as *forgotten* features and examples and we refer to the features  
 195 and examples in  $(\text{feat}(E) \cup E) \setminus \chi(B_b)$  as *future* features and examples. We start with some  
 196 simple observations that follow immediately from the properties of tree decompositions.

todo: adjust to  
NLC-width

197 ► **Observation 6.**(1)  $e(f) = 0$  for every forgotten example  $e \in \text{exam}(B_b) \setminus \text{exam}(b)$  and  
 198 future feature  $f \in \text{feat}(E) \setminus \text{feat}(B_b)$ ,  
 199 (2)  $e(f) = 0$  for every future example  $e \in E \setminus \text{exam}(B_b)$  and forgotten feature  $f \in \text{feat}(B_b) \setminus$   
 200  $\text{feat}(b)$ ;

201 **Proof.** Towards showing (1), let  $e$  be an example in  $\text{exam}(B_b) \setminus \text{exam}(b)$  and let  $f$  be a  
 202 feature in  $\text{feat}(E) \setminus \text{feat}(B_b)$ . We claim that because  $(T, \chi)$  is a tree decomposition of  $G_I(E)$ ,  
 203 the graph  $G_I(E)$  cannot contain an edge between  $e$  and  $f$ , which implies that  $e(f) = 0$ .  
 204 Suppose for a contradiction that this is not the case, i.e.  $\{e, f\} \in E(G_I(E))$ . Then, because  
 205 of property (T1) of a tree decomposition, there must exist a node  $b'$  such that  $e, f \in \chi(b')$ .  
 206 But then, if  $b' \in V(B_b)$  we obtain that  $f \notin \chi(b')$ . Similarly, if  $b' \in V(B \setminus B_b)$ , we obtain  
 207 that  $e \notin \chi(b')$  since otherwise  $e$  would violate property (T2) of a tree decomposition. This  
 208 completes the proof for (1); the proof for (2) is analogous. ◀

209 Informally, Observation 6 shows that forgotten examples cannot be distinguished by  
 210 future features and future examples cannot be distinguished by forgotten features. Consider  
 211 a DT  $T$  for  $E$  and a node  $b$  of  $B$ . For a set  $W$  containing features and examples from  $E$ , we  
 212 denote by  $E[W]$  the sub-instance of  $E$  induced by the features and examples in  $W$ . Our aim  
 213 is to obtain a compact representation (represented by records) of the partial solution for the  
 214 sub-instance  $E[\chi(B_b)]$  of  $E$  induced by the features and examples in  $\chi(B_b)$  represented by  $T$ .

215 Intuitively, such a compact representation has to (1) represent a partial solution (DT)  
 216 for the examples in  $\text{exam}(B_b)$  and (2) retain sufficient information about the structure of  $T$   
 217 in order to decide whether it can be extended to a DT that also classifies the examples in  
 218  $E \setminus \text{exam}(B_b)$ .

219 For illustration purposes let us first consider the simplified case that  $\text{exam}(b) = \emptyset$ . Because  
 220 of Observation 6 (1), this implies that every forgotten example goes to the left child of  
 221 any node  $t$  in  $T$  that is assigned a future feature. Therefore, under the assumption that  
 222  $\text{exam}(b) = \emptyset$  the DT  $T'$  obtained from  $T$  after:

223 ■ removing the subtree  $T_r$  of  $T$  for every right child  $r$  of a node  $t$  of  $T$  with  $\text{feat}(t) \in$   
 224  $\text{feat}(E) \setminus \text{feat}(B_b)$  and replacing  $t$  with an edge from its parent in  $T$  to its left child in  $T$

225 is a DT for  $E[\chi(B_b)]$ . Note that this means that under the rather strong assumption  
 226 that  $\text{exam}(b) = \emptyset$ , the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$  is itself a DT  
 227 using only features in  $\text{feat}(B_b)$ ; we will see later that unfortunately this is no longer the case  
 228 if  $\text{exam}(b) \neq \emptyset$ . Note that even though  $T'$  is a DT for  $E[B_b]$ , it does not yet constitute a  
 229 compact representation, since the number of features it uses in  $\text{feat}(B_b) \setminus \text{feat}(b)$  is potentially  
 230 unbounded. However, we obtain from Observation 6 (2) that every future example will end  
 231 up in the left child of every node  $t$  of  $T'$  that is assigned a forgotten feature. This means  
 232 that to decide whether  $T'$  can be extended to a DT for the whole instance, the nodes that  
 233 are assigned forgotten features are not important. In fact, the only nodes in  $T'$  that can be  
 234 important for the classification of future examples are the nodes that are assigned features  
 235 in  $\text{feat}(b)$ . That is, it is sufficient to remember the DT  $T''$  obtained from  $T'$  after:

236 ■ removing the subtree  $T_r$  of  $T'$  for every right child  $r$  of a node  $t$  of  $T'$  with  $\text{feat}(t) \in$   
 237  $\text{feat}(B_b) \setminus \text{feat}(b)$  and replacing  $t$  with an edge from its parent in  $T'$  to its left child in  $T'$ .

238 Since the number of possible DT  $T''$  is clearly bounded in terms of the number of features  
 239 in  $\text{feat}(b)$  (and therefore in terms of the treewidth of  $G_I(E)$ ), this would already give us the  
 240 compact representation that we are looking for. However, this only works in the case that  
 241  $\text{exam}(b) = \emptyset$ , which is clearly not the case in general.

242 So let us now consider the general case with  $\text{exam}(b) \neq \emptyset$ . The first difference now is  
 243 that the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$  is no longer a DT that only  
 244 uses features in  $\text{feat}(B_b)$ . In fact, it could even be the case that  $E[\chi(B_b)]$  does not have a  
 245 DT, because there could exist examples in  $\text{exam}(b)$  that can only be distinguished using  
 246 the features in  $\text{feat}(E) \setminus \text{feat}(B_b)$ . This means that we have to allow our partial solution for  
 247  $E[\chi(B_b)]$  to use future features. Fortunately, we do not need to know which exact future  
 248 feature is used by our partial solution but it suffices to know that a future feature is used and  
 249 how it behaves w.r.t. the examples in  $\text{exam}(b)$ ; this is because Observation 6 (1) implies that  
 250 a future feature is used in a partial solution only for the purpose of distinguishing examples  
 251 in  $\text{exam}(b)$ . Moreover, because every forgotten example ends up in the left child of any node  
 252  $t$  of  $T$  that uses a future feature, we only need to remember the left child for those nodes.  
 253 Also, we only need to remember occurrences of those nodes (using future features) if at least  
 254 one example in  $\text{exam}(b)$  ends up to in the right child of such a node; otherwise the node has  
 255 no influence on the classification of examples in  $\text{exam}(B_b)$ . Finally, we cannot simply forget  
 256 nodes that use forgotten features (as we could in the case that  $\text{exam}(b) = \emptyset$ ). This is because  
 257 we need to know exactly where the examples in  $\text{exam}(b)$  end up at. For instance, if such  
 258 an example in  $\text{exam}(b)$  ends up in the right child of a node using a future feature, we need  
 259 to know that this is the case because this means that the example has to be classified in  
 260 this place at a later stage of the algorithm. Nevertheless, we do not need to remember all  
 261 occurrences of nodes using forgotten features, but only those for which there is at least one  
 262 example in  $\text{exam}(b)$  that ends up in the right child of the node. Similarly, we do not need  
 263 to remember the exact forgotten feature that is used but only how it behaves towards the  
 264 examples in  $\text{exam}(b)$ . In summary, we only need to remember the full information about  
 265 the nodes of  $T$  that use a feature in  $\text{feat}(b)$ . For all other nodes, i.e. nodes that use either  
 266 forgotten or future features, we only need to remember such a node, if at least one example  
 267 in  $\text{exam}(b)$  ends up in its right child. Moreover, even if this is the case, we only need to  
 268 remember the following for such nodes:

269 ■ whether it uses a future or a forgotten feature and

270 ■ how it behaves w.r.t. the examples in  $\text{exam}(b)$ .

271 With these ideas in mind, we are now ready to provide a formal definition of the compact  
272 representation of the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$ .

### 273 3.2 Formal Definition of Records and Preliminary Results

274 In the following, let  $E$  be a CI and let  $B$  be a  $k$ -NLC-expression tree for  $G_I(E)$ . Consider a  
275 node  $b$  of  $B$ . Recall that  $b$  is either a leaf node associated with a  $k$ -graph  $i(v)$ , a relabelling  
276 node with 1 child and with relabelling function  $R_b$ , or a join node with a left child, a right  
277 child and a join matrix  $M_b$ . Moreover, recall that  $(G_b, \lambda_b)$  is the  $k$ -graph associated with  $b$   
278 (whose unlabeled version is a subgraph of  $G$ ) and  $V_b$  is the set of vertices of  $G_b$ . Additionally,  
279 we will use the following notation. We denote by  $\text{feat}(b)$  the set  $V_b \cap \text{feat}(E)$  of features in  
280  $V_b$  and by  $\text{exam}(b)$  the set  $V_b \cap E$  of examples in  $V_b$ .

281 Consider a node  $b$  of  $B$ . Let  $L$  be a set of labels (usually  $L = [k]$ ). For a subset  $L' \subseteq L$ ,  
282 we denote by  $\overline{L'}$  the set  $L \setminus L'$ . For a label  $l \in L$ , we introduce a new feature  $f_l$ , which we  
283 will call a *forgotten feature*. Moreover, for a subset  $L' \subseteq L$  of labels, we introduce a new  
284 feature  $f_{L'}$ , which we call an *future (or introduce) feature*. Let  $F_L = \{f_l \mid l \in L\}$  be the set  
285 of all forgotten features and let  $I_L = \{f_{L'} \mid L' \subseteq L\}$  be the set of all future features w.r.t.  $L$ .  
286 To distinguish features in  $\text{feat}(E)$  from forgotten and future features, we will refer to them  
287 as *real features*.

definition of new  
features

288 Let  $T$  be a decision tree and  $t \in V(T)$ . We say that a node  $t_A$  is a *left/right ancestor*  
289 of  $t$  if  $t$  is contained in the subtree of  $T$  rooted at the left/right child of  $t_A$ . We denote by  
290  $\text{anc}_L(t)/\text{anc}_R(t)$  the set of all left/right ancestors of  $t$  in  $T$ . We denote by  $\text{anc}(t)$  the set of  
291 all *ancestors* of  $t$  in  $T$ , i.e.,  $\text{anc}(t) = \text{anc}_L(t) \cup \text{anc}_R(t)$ .

292 Let  $T$  be a decision tree and  $t \in V(T)$  be an inner node of  $T$  with left child  $l$ , right child  
293  $r$ , and parent  $p$ . We say that  $T'$  is obtained from  $T$  after *left/right-contracting*  $t$  if  $T'$  is the  
294 decision tree obtained from  $T$  after removing  $t$  together with all nodes in  $T_r/T_l$  and adding  
295 the edge between  $p$  and  $l/r$ ; if  $t$  has no parent then no edge is added.

296 We say that  $T$  is a *decision tree* for  $b$ , if  $T$  is a decision tree for  $\text{exam}(b)$  that uses only  
297 the features in  $\text{feat}(b)$ . We say that an inner node  $t \in V(T)$  is *left/right redundant* in  $T$  if  
298  $\text{feat}(t) \in \text{feat}(\text{anc}_L(t))/\text{feat}(t) \in \text{feat}(\text{anc}_R(t))$ . We say that  $t$  is redundant if it is either left  
299 redundant or right redundant. Intuitively, a node  $t$  is left/right redundant if all examples  
300 that end up at  $t$ , i.e., the examples  $E_T(t)$ , go the left/right child of  $t$  in  $T$ . Therefore, if  $t$   
301 is left/right redundant in  $T$ , then the tree obtained after left/right-contracting  $t$  is still a  
302 decision tree.

303 We say that  $T$  is a *decision tree template* for  $b$  if  $T$  is a decision tree for  $\text{exam}(b)$  that can  
304 additionally use the future features in  $I_{[k]}$ . Here, we assume that a future feature  $f_{L'} \in I_{[k]}$   
305 for some  $L' \subseteq [k]$  is 1 at an example  $e \in \text{exam}(b)$  if  $\lambda_b(e) \in L'$  and otherwise it is 0. We say  
306 that a decision tree template is *complete* if it does not use any features in  $I_{[k]}$ , otherwise  
307 we say that it is *incomplete*. Informally, the role of the future features in a decision tree  
308 template is provide placeholders for the features in  $\text{feat}(E) \setminus \text{feat}(b)$ . Because all of those  
309 features behave the same w.r.t. to examples in  $\text{exam}(b)$  having the same label, they can  
310 be characterized by the set of labels for which those features are 1. Let  $T$  be a decision  
311 tree template for  $b$  and let  $t \in V(T)$ . We denote by  $A(t)$  the set of *filtered labels* for  $t$ , i.e.,  
312  $A(t) = (\bigcap_{f_{L'} \in \text{feat}(\text{anc}_L(t)) \cap I_{[k]}} \overline{L'}) \cap (\bigcap_{f_{L'} \in \text{feat}(\text{anc}_R(t)) \cap I_{[k]}} L')$ . Informally,  $A(t)$  is the set of all  
313 labels  $l \in [k]$  such that an example  $e$  with label  $l$  would end up at  $t$ , if only the effect of  
314 the future features on the path to  $t$  is considered. We say that  $t$  with  $f_{L'} = \text{feat}(t) \in I_{[k]}$  is  
315 *left/right redundant* in  $T$  if  $A(t) \subseteq L'/A(t) \subseteq \overline{L'}$ . We say that  $t$  is *redundant* if it is either

left-redundant or right-redundant. Intuitively,  $t$  is left/right redundant if all examples that can reach  $t$  (considering the influence of the future features only) end up in the left/right child of  $t$ . This also implies that if  $t$  is left/right redundant then the decision tree obtained after left/right contracting  $t$  is equivalent with  $T$  (all examples end up in the same leaves).

We say that  $T$  is a *decision tree skeleton* for  $b$  if  $T$  is a decision tree that can only use features in  $F_{[k]} \cup I_{[k]}$ . Note that because of the features  $F_{[k]}$ , whose behaviour w.r.t. the examples in  $\text{exam}(b)$  is not defined, the behaviour w.r.t. the examples in  $\text{exam}(b)$  of such a DT skeleton is not necessarily defined. Nevertheless, the behaviour of a feature  $f_l$  in  $F_{[k]}$  is well-defined w.r.t. to the examples in  $\text{exam}(E) \setminus \text{exam}(b)$ , i.e., it behaves the same as any feature in  $\text{feat}(b)$  with label  $l$ . Intuitively, decision tree skeletons are obtained from decision tree templates after replacing every feature  $f$  in  $\text{feat}(b)$  with its label  $\lambda_b(f)$ . This allows us to further compress the information contained in decision tree templates, while still keeping the information about how the decision tree template behaves w.r.t. future examples in  $\text{exam}(b)$ . In particular, decision tree skeletons will form the main information stored by our records.

Let  $T$  be a decision tree skeleton and  $t \in V(T)$ . Similarly as we did for decision tree templates, we say that  $T$  is *complete* if it uses no future features and otherwise we say that it is *incomplete*. We say that an inner node  $t$  with  $f_l = \text{feat}(t) \in F_{[k]}$  is *left/right redundant* in  $T$  if  $f_l \in \text{feat}(\text{anc}_L(t)) / f_l \in \text{feat}(\text{anc}_R(t))$ . Similarly, as for decision tree (templates), if  $t$  is left/right redundant, then we can left/right contract  $t$  without changing the properties of  $T$ .

Let  $T$  be a decision tree (skeleton/template). Then, we denote by  $r(T)$  the decision tree obtained from  $T$  after left/right contracting every left/right redundant node of  $T$ . Note that if  $T$  is a decision tree (skeleton/template) for  $b$ , then so is  $r(T)$ .

**Proof.**

◀

definition of relabelling

344

Let  $T$  be a decision tree. A *feature relabeling* for  $T$  is a function  $\alpha : F' \rightarrow \text{feat}(E) \cup F_L \cup I_L$ , where  $F' \subseteq \text{feat}(T)$  and  $L$  is some set of labels (usually  $L = [k]$ ). With a slight abuse of notation, we denote by  $\alpha(T)$ , the decision tree obtained after relabeling all features in  $F'$  (used by  $T$ ) according to  $\alpha$ , i.e.,  $\alpha(T)$  is obtained from  $T$  after replacing the feature assignment function  $\text{feat}_T(t)$  for  $T$  with the function  $\text{feat}_{\alpha(T)}(t)$  defined by setting  $\text{feat}_{\alpha(T)}(t) = \alpha(\text{feat}_T(t))$  if  $\text{feat}(t) \in F'$  and  $\text{feat}_{\alpha(T)}(t) = \text{feat}_T(t)$ , otherwise. We say that two feature relabellings  $\alpha_1 : F_1 \rightarrow \text{feat}(E) \cup F_L \cup I_L$  and  $\alpha_2 : F_2 \rightarrow \text{feat}(E) \cup F_L \cup I_L$  are *compatible* if they agree on their shared domain  $F_1 \cap F_2$ .

We denote by  $\alpha_b^s$  the *standard feature relabelling* for  $b$ , i.e., the function  $\alpha_b^s : \text{feat}(b) \rightarrow [k]$  defined by setting  $\alpha_b^s(f) = \lambda_b(f)$  for every  $f \in \text{feat}(b)$ .

Semantics of records

353

We are now ready to define the records and their semantics. A *record* for  $b$  is a pair  $(T, s)$  such that  $T$  is a reduced decision tree skeleton for  $b$  and  $s$  is a natural number. We say that a record  $(T, s)$  is *valid* for  $b$  if  $s$  is the minimum number such that there is a (reduced) decision tree template  $T'$  for  $b$  such that  $r(\alpha_b^s(T')) = T$  and  $s = |V(T') \setminus V(T)|$ . We denote by  $\mathcal{R}(b)$  the set of all valid records for  $b$ . The following corollary follows immediately from Lemma 8.

► **Corollary 9.**  $|\mathcal{R}(b)| \leq ?$

359

360 Note that  $E$  has a DT of size at most  $s$  if and only if  $\mathcal{R}(r)$  contains a record  $(T, s)$  such that  
 361  $T$  is complete, where  $r$  is the root of  $B$ . ...

362 ► **Lemma 10.** *Let  $T$  be a decision tree and let  $\alpha$  be a feature relabelling for  $T$ . Then,*  
 363  $r(\alpha(T)) = r(\alpha(r(T)))$ .

364 ► **Observation 11.** *Let  $T$  be a decision tree and let  $\alpha_1$  and  $\alpha_2$  be two compatible feature*  
 365 *relabelling for  $T$ . Then,  $\alpha_1\alpha_2(T) = \alpha_2\alpha_1(T)$ .*

### 366 3.3 Proof to the Main Result

367 We will now show that we can compute  $\mathcal{R}(b)$  for every of the 3 node types of a nice  $k$ -NLC  
 368 expression tree provided that  $\mathcal{R}(c)$  has already been computed for every child  $c$  of  $b$ .

369 ► **Lemma 12** (leaf node). *Let  $b \in V(B)$  be a leaf node. Then  $\mathcal{R}(b)$  can be computed in time*  
 370 *??.*

371 **Proof.** Let  $i(v)$  be the initial  $k$ -graph associated with  $b$ . If  $v$  is a feature, then  $\mathcal{R}(b)$  contains  
 372 all records  $(T, 0)$  such that  $T$  is a reduced decision tree skeleton for  $b$  using only the features  
 373 in  $\{f_{\lambda(v)}\} \cup I_{[k]}$ . The correctness in this case follows because  $V_b$  contains no examples and  
 374 therefore every reduced decision tree skeleton constitutes a valid record for  $b$ . Moreover, the  
 375 run-time follows from Lemma ??, since the time required to enumerate all those reduced  
 376 decision tree skeletons is at most  $\mathcal{O}(?)$ .

377 If, on the other hand  $v$  is an example, then  $\mathcal{R}(b)$  contains all records  $(T, 0)$  such that  $T$   
 378 is a reduced decision tree skeleton for  $b$  using only the features in  $I_{[k]}$  and which correctly  
 379 classify  $v$ . Because of Lemma ??, those can be enumerated in time  $\mathcal{O}(?)$  and checking for  
 380 each of those whether it correctly classifies  $v$  can be achieved in time  $\mathcal{O}(?)$ .

todo: show  
correctness

382 ► **Lemma 13** (join node). *Let  $b \in V(B)$  be a join node. Then  $\mathcal{R}(b)$  can be computed in time*  
 383  $\mathcal{O}(k(2k + 2^k + 2)2^{6k+1})$ .

384 **Proof.** Let  $b_L$  and  $b_R$  be the left and right child of  $b$  in  $B$ , respectively.

385 Let  $M_b$  be the join matrix for the node  $b$ , i.e.,  $M_b$  is a  $k \times k$  binary matrix. For every  
 386 label  $i \in [k]$ , let  $A_{i,*} = \{j \in [k] \mid M_b[i, j] = 1\}$  and  $A_{*,i} = \{j \in [k] \mid M_b[j, i] = 1\}$ .

387 To distinguish between forgotten features from the left and the right subtree, we introduce  
 388 the left  $i_L$  and the right version  $i_R$  for every label  $i \in [k]$ . With a slight abuse of notation,  
 389 we also denote by  $[k_L]$  be the set  $\{1_L, \dots, k_L\}$  of (left) labels and we denote by  $[k_R]$  be the  
 390 set  $\{1_R, \dots, k_R\}$  of (right) labels.

391 To compute the set  $\mathcal{R}(b)$  of valid record for  $b$ , we first enumerate all reduced DT skeletons  
 392  $T$  using features in  $[k_L] \cup [k_R] \cup I_{[k]}$ . Because of Lemma 17, those can be enumerated in time  
 393  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$ .

394 For every such reduced DT skeleton  $T$ , we now do the following in order to decide whether  
 395  $T$  gives rise to a valid record for  $b$ . Let  $\alpha^{LR \rightarrow} : F_{[k_L]} \cup F_{[k_R]} \rightarrow F_{[k]}$  be the feature relabeling  
 396 that relabels every (left/right) feature  $f_{i_H} \in F_{[k_L]} \cup F_{[k_R]}$  (for some  $H \in \{L, R\}$ ) to its  
 397 original feature  $f_i$ .

398 Let  $\alpha^L : F_{[k_R]} \rightarrow I_{[k]}$  be the feature relabeling that relabels every forgotten feature  
 399  $f_{i_R} \in F_{[k_R]}$  to the future feature  $f_{A_{*,i}}$ . Let  $T_L$  be the reduced DT skeleton obtained from  $T$   
 400 after applying the relabelling using  $\alpha^L$  followed by  $\alpha^{LR \rightarrow}$  and then reducing the resulting  
 401 DT skeleton, i.e.,  $T_L = r(\alpha^{LR \rightarrow}(\alpha^L(T)))$ .

402 Similarly, let  $\alpha^R : F_{[k_L]} \rightarrow I_{[k]}$  be the feature relabeling that relabels every forgotten  
 403 feature  $f_{i_L} \in F_{[k_L]}$  to the future feature  $f_{A_{i,*}}$ . Let  $T_R$  be the reduced DT skeleton obtained

from  $T$  after applying the relabelling using  $\alpha^R$  followed by  $\alpha^{LR \rightarrow}$  and then reducing the resulting DT skeleton, i.e.,  $T_R = r(\alpha^{LR \rightarrow}(\alpha^R(T)))$ .

Let  $\hat{T} = \alpha^{LR \rightarrow}(T)$  and  $\hat{s} = |V(T) \setminus V(\hat{T})|$ . We now check whether there are records  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$ . If not we discard  $T$  and if yes, then we add the record  $(\hat{T}, s_L + s_R + \hat{s})$  to  $\mathcal{R}(b)$ . This completes the description about how the records  $\mathcal{R}(b)$  are computed. Moreover, the run-time for computing  $\mathcal{R}(b)$  can be obtained as follows. First, because of Lemma 17, we can enumerate all reduced DT skeletons  $T$  in time  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$ . Moreover, computing  $\hat{T}$  and  $\hat{s}$  can be done in time  $\mathcal{O}(|T|) = \mathcal{O}(s)$ . Finally, computing  $T_L$  and  $T_R$  and checking the existence of the records  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$  can be achieved in time  $\mathcal{O}(?)$ . Therefore, we obtain  $\mathcal{O}(?)$  as the total run-time for computing  $\mathcal{R}(b)$ .

We now show the correctness of our construction for  $\mathcal{R}(b)$ , i.e., we have to show that a record  $(T, s)$  is valid if and only if we have added such a record according to our construction above.

Towards showing the forward direction, suppose that  $(\hat{T}, s)$  is a valid record in  $\mathcal{R}(b)$ . Therefore, there is a DT template  $T'$  for  $b$  such that  $\hat{T} = r(\eta_{\alpha_b^s}(T'))$  and  $s = |V(T') \setminus V(\hat{T})|$ .

Because  $\hat{T}$  is obtained from  $T'$  by reduction, every node in  $\hat{T}$  corresponds to a unique node in  $T'$ . Therefore, there is an injective function  $z_H : V(\hat{T}) \rightarrow V(T')$  mapping every node in  $\hat{T}$  to its original node in  $T'$ . Let  $T$  be the DT obtained from  $\hat{T}$  after by setting  $feat_T(t) = i_H$  if  $feat_{\hat{T}}(t) = i$  and  $feat_{T'}(t) \in feat(b_H)$  for  $H \in \{L, B\}$ .

Note that  $\hat{T} = \eta_{\alpha^{LR \rightarrow}}(T)$  and  $\hat{T}$  is reduced because  $(\hat{T}, s) \in \mathcal{R}(b)$ .

Let  $\alpha^{\rightarrow R} : F_{[k]} \rightarrow F_{[k_R]}$  ( $\alpha^{\rightarrow L} : F_{[k]} \rightarrow F_{[k_L]}$ ) be the feature relabeling that relabels every forgotten feature  $f_i \in F_{[k]}$  to its corresponding forgotten feature in  $[k_R]$  ( $[k_L]$ ), i.e.,  $\alpha^{\rightarrow R}(i) = i_R$  ( $\alpha^{\rightarrow L}(i) = i_L$ ) for every  $i \in [k]$ .

Note that  $T = r(\eta_{\alpha^{\rightarrow L}}(\eta_{\alpha_{b_L}^s}(\eta_{\alpha^{\rightarrow R}}(\eta_{\alpha_{b_R}^s}(T')))))$ .

Let  $T_L = r(\eta_{\alpha^L}(T))$  and  $T_R = r(\eta_{\alpha^R}(T))$ . It remains to show that there are  $s_L$  and  $s_R$  with  $s = s_L + s_R$  such that  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$ .

Let  $T'_L = r(\eta_{\alpha^L}(\eta_{\alpha^{\rightarrow R}}(\eta_{\alpha_{b_R}^s}(T')))))$  and  $T'_R = r(\eta_{\alpha^R}(\eta_{\alpha^{\rightarrow L}}(\eta_{\alpha_{b_L}^s}(T')))))$ .

Note that  $T_L = r(\eta_{\alpha_{b_L}^s}(T'_L))$  because of Lemma ?? and the observation that  $\eta_{\alpha_{b_L}^s} \circ \eta_{\alpha^L} \circ \eta_{\alpha^{\rightarrow R}} \circ \eta_{\alpha_{b_R}^s} = ?$ .

Towards showing the reverse direction, suppose that our construction adds the record  $(\hat{T}, s_L + s_R)$  and let  $T, T_L, T_R$  be as defined in the construction. Recall that:

- $\hat{T}$  is reduced and  $\hat{T} = \eta_{\alpha^{LR \rightarrow}}(T)$ ,
- $T_L = r(\eta_{\alpha^L}(T))$  and  $(T_L, s_L) \in \mathcal{R}(b_L)$ ,
- $T_R = r(\eta_{\alpha^R}(T))$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$ .

Let  $T'_L$  be the reduced DT template for  $b_L$  such that  $T_L = r(\eta_{\alpha_{b_L}^s}(T'_L))$  and  $s_L = |V(T'_L) \setminus V(T_L)|$ , which exists because  $(T_L, s_L) \in \mathcal{R}(b_L)$ . Similarly, let  $T'_R$  be the reduced DT template for  $b_R$  such that  $T_R = r(\eta_{\alpha_{b_R}^s}(T'_R))$  and  $s_R = |V(T'_R) \setminus V(T_R)|$ , which exists because  $(T_R, s_R) \in \mathcal{R}(b_R)$ .

We now show how to construct a witness  $T'$  (from  $T, T'_L$ , and  $T'_R$ ) for the validity of the record  $(\hat{T}, s_L + s_R)$ , i.e.,  $T'$  is a reduced DT template for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$  and  $s_L + s_R = |V(T') \setminus V(\hat{T})|$ .

Suppose that there is a reduced DT template  $T'$  for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$  and  $|V(T') \setminus V(\hat{T})| < s_L + s_R$ .

Informally, we obtain  $T'$  from  $T$  after reversing the relabelling and reduction operations applied to  $T'_L$  and  $T'_R$  to obtain  $T_L$  and  $T_R$ , respectively; recall that  $T_H = r(\eta_{\alpha_{b_H}^s}(T'_H))$  for

done using the  
forward direction!

$H \in \{L, R\}$ . That is, we will reverse the labelling for the nodes in  $T$  and add back the nodes to  $T$  that have been removed from  $T'_L$  and  $T'_R$ .

Let  $H \in \{L, R\}$ . Because  $T_H$  is obtained from  $T$  by reduction, every node in  $T_H$  corresponds to a unique node in  $T$ . Therefore, there is an injective function  $x_H : V(T_H) \rightarrow V(T)$  mapping every node in  $T_H$  to its original node in  $T$ . Similarly, because  $T_H$  is obtained from  $T'_H$  by reduction, there is an injective function  $y_H : V(T_H) \rightarrow V(T'_H)$  mapping every node in  $T_H$  to its original node in  $T'_H$ . See also Figure 2 for an illustration of these mappings.

Figure 2

Our first order of business is to rename all forgotten features in  $T$  to their real features as given by  $T'_L$  and  $T'_R$ . That is, for every node  $t$  in  $T$  assigned to a forgotten feature, i.e.,  $feat(t) \in F_{[k_L]} \cup F_{[k_R]}$ , we do the following. If  $feat(t) \in F_{[k_H]}$  for  $H \in \{L, R\}$ , then  $t$  is also in  $T_H$  and hence also in  $T'_H$ . Therefore, we can change  $feat(t)$  to the real feature assigned to  $t$  in  $T'_H$ . Let  $T^0$  be the DT obtained from  $T$  after renaming all forgotten features to real features in this manner.

Consider an edge  $e = (p, c)$  in  $T_L$  such that  $p$  is the parent of  $c$  in  $T_L$ . Then,  $e$  corresponds to a path  $P'_L(e)$  between  $y_L(p)$  and  $y_L(c)$  in  $T'_L$ . Similarly,  $e$  corresponds to a path  $P_L(e)$  between  $x_L(p)$  and  $x_L(c)$  in  $T^0$ .

Our next order of business is now to add all nodes to  $T^0$  that have been removed when going from  $T'_L$  to  $T_L$  (via the reduction  $r(\eta_{\alpha_{b_L}^s}(T'_L))$ ). To achieve this, we go over every edge  $e = (p, c)$  of  $T_L$  such that  $p$  is the parent of  $c$  in  $T_L$  and plugin the path  $P'_L(e)$  (from  $T'_L$ ) into the last edge on the path  $P_L(e)$  (from  $T^0$ ). Let  $T^1$  be the tree obtained from  $T^0$  after doing this operation for every edge of  $T_L$ .

Consider an edge  $e = (p, c)$  in  $T_R$  such that  $p$  is the parent of  $c$  in  $T_R$ . Then,  $e$  corresponds to a path  $P'_R(e)$  between  $y_R(p)$  and  $y_R(c)$  in  $T'_R$ . Similarly,  $e$  corresponds to a path  $P_R(e)$  between  $x_R(p)$  and  $x_R(c)$  in  $T^1$ . Similarly to above, we now add all nodes to  $T^1$  that have been removed when going from  $T'_R$  to  $T_R$  (via the reduction  $r(\eta_{\alpha_{b_R}^s}(T'_R))$ ). To achieve this, we go over every edge  $e = (p, c)$  of  $T_R$  such that  $p$  is the parent of  $c$  in  $T_R$  and plugin the path  $P'_R(e)$  (from  $T'_R$ ) into the last edge on the path  $P_R(e)$  (from  $T^1$ ). Let  $T'$  be the tree obtained from  $T^1$  after doing this operation for every edge of  $T_R$ .

We now show that  $T'$  is indeed a witness for the validity of the record  $(\hat{T}, s_L + s_R)$ , i.e.,  $T'$  is a reduced DT template for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$  and  $s_L + s_R = |V(T') \setminus V(\hat{T})|$ .

We start by showing that  $\hat{T} = r(\eta_{\alpha_b^s}(T'))$ . Because  $\hat{T} = \alpha_b^s(T^0)$ , it suffices to show that the only nodes removed from  $T'$  are the ones that we added to  $T^0$  to obtain  $T'$ . Or in other words, we need to show that only the nodes that are redundant in  $\eta_{\alpha_b^s}(T')$  are the nodes in  $V(T') \setminus V(T^0)$ .

Consider a node  $t \in V(T') \setminus V(T^0)$ , i.e.,  $t$  is a node that we added to  $T^0$  to obtain  $T'$ . Then,  $t \in V(T'_H) \setminus V(T_H)$  for some  $H \in \{L, R\}$ . Because  $T_H = r(\eta_{\alpha_{b_H}^s}(T'_H))$ ,  $t$  is redundant in  $\eta_{\alpha_{b_H}^s}(T'_H)$ , because of some node  $t' \in V(T_H)$  with  $\alpha_{b_H}^s(fe_{T'_H}(t)) = \alpha_{b_H}^s(fe_{T'_H}(t'))$ . Since  $t' \in V(T_H)$  also  $t' \in V(T')$  and therefore  $t$  is also redundant in  $\eta_{\alpha_b^s}(T')$  (because of  $t'$ ), as required.

Now consider a node  $t \in V(T^0)$  and assume for a contradiction that  $t$  is redundant in  $\alpha_b^s(T')$  because of some node  $t' \in V(T')$  with  $\alpha_b^s(\text{feat}_{T'}(t)) = \alpha_b^s(\text{feat}_{T'}(t'))$ . Then, because  $\hat{T} = \alpha_b^s(T^0)$  is reduced, we obtain that  $t' \in V(T') \setminus V(T^0)$ . Therefore,  $t' \in V(T'_H) \setminus V(T_H)$  for some  $H \in \{L, R\}$ . But then,  $t'$  is redundant in  $\eta_{\alpha_b^s}(T'_H)$  because of some node  $t'' \in V(T_H)$  with  $\alpha_b^s(\text{feat}_{T'}(t')) = \alpha_b^s(\text{feat}_{T'_H}(t''))$ , which implies that also  $t$  is redundant in  $\hat{T}$  because of  $t''$  a contradiction to our assumption that  $\hat{T}$  is reduced. This shows that  $\hat{T} = r(\eta_{\alpha_b^s}(T'))$ . Moreover, because  $|V(T^0)| = |V(\hat{T})|$  and  $|V(T') \setminus V(T^0)| = s_L + s_R$ , it also follows that  $s_L + s_R = |V(T') \setminus V(\hat{T})|$ .

Moreover,  $V(T) \setminus \text{Im}(x_H)$  and  $V(T'_H) \setminus \text{Im}(y_H)$  can be partitioned into subtrees that have been deleted after the application of  $r \circ p_*$ ,  $r \circ p'_*$  on  $T$  or of the standard reduction on  $T'_H$ : let  $X_H^*$  and  $Y_H^*$  be the set of roots of the above subtrees in  $V(T) \setminus \text{Im}(x_H)$  and  $V(T'_H) \setminus \text{Im}(y_H)$  respectively. In addition, for every element  $y \in Y_H^*$ , let  $Y_y^H$  be the maximal subtree of  $T'_H$  rooted at  $y$  with no elements from  $\text{Im}(y_H)$  and that does not contain any vertex from  $Y_H^* \setminus \{y\}$ ; let  $(Y_y^H, S_y^H)$  the corresponding single pair. In a similar way, for every element  $x \in X_H^*$ , let  $X_x^H$  be the maximal subtree of  $T$  rooted at  $x$  with no elements from  $\text{Im}(x_H)$  and that does not contain any vertex from  $X_H^* \setminus \{x\}$ ; let  $(X_x^H, S_x^H)$  the corresponding single pair. Finally, for every  $y \in Y_H^*$ , let  $P_y^H$  be the shortest downwards path in  $T'_H$  that contains  $y$  and with both endpoints in  $\text{Im}(y_H)$ , say  $y_H(t)$  and  $y_H(t')$ .

*Claim 1: For every  $H \in \{L, R\}$  and for every  $y, y' \in Y_H^*$ , the paths  $P_y^H$  and  $P_{y'}^H$  are either edge disjoint or  $P_y^H = P_{y'}^H$ .*

*Proof.* If  $P_y^H$  and  $P_{y'}^H$  are edge disjoint, then the statement is proven immediately. Suppose  $P_y^H$  and  $P_{y'}^H$  share an edge. By minimality and the fact they are downwards paths,  $P_y^H$  and  $P_{y'}^H$  share the endpoint towards the root. If they also share the other endpoint, then the statement is proven immediately. Suppose now their endpoints towards the leaves is different, say  $w$  and  $w'$ , and consider the last edge those paths have in common in a root-to-leaf order, say  $uv$ .

Without loss of generality, we can assume  $w$  belongs to the left branch of  $v$  and  $w'$  belongs to the right branch of  $v$ . Note that  $v \in V(T'_H) \setminus \text{Im}(y_H)$ , or we get a contradiction due the minimality of  $P_y^H$ . Now we get the following contradiction: by construction,  $w$  and  $w'$  are both elements of  $\text{Im}(y_H)$  but at least one of them must be in  $V(T'_H) \setminus \text{Im}(y_H)$  since it is an element of either  $Y_y^H$  or of  $Y_{y'}^H$ . This proves Claim 1.

Now for every  $y \in Y_H^*$  we consider the path  $Q_y^H$  in  $T$  having endpoints  $x_H(t)$  and  $x_H(t)$ .

Now we are able to describe how to obtain a witness  $T'$  of  $T$  for  $b$ . For every  $y \in Y_L^*$ , in the last edge of path  $Q_y^L$  we plug in the single pair  $(Y_{y'}^L, S_{y'}^L)$  rooted at  $y'$ , for every internal node  $y'$  of  $P_y^L$ , in the order the nodes  $y'$  appear in  $P_y^L$ . Note that, in the case an element of  $Y_L^*$  is present in more than one  $P_y^L$ , we plug in the corresponding single pair only once. Note also that whenever we plug in some single pair  $(Y_{y'}^L, S_{y'}^L)$  in a DT, the tree  $Y_{y'}^L$  has real features and future features as nodes. Call this graph  $T^*$ . Now we do the same sequence of plug ins of the single pairs corresponding to the internal vertices of  $P_y^R$  in the last edge of the path  $Q_y^R$ . Again, in the case an element of  $Y_R^*$  is present in more than one  $P_y^R$ , we plug in the corresponding single pair only once. Call the tree obtained in this way  $T'$ . Note that  $T'$  contains real features from  $\text{feat}(b_L)$  and from  $\text{feat}(b_R)$  and future features with labels in  $\mathcal{P}([k])$ .

To conclude this part of the proof we have to show two things: (i)  $T$  is obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a real DT for  $b$ . We start proving (i): by construction  $T'$  is obtained from  $T$  after adding  $s_L$  elements from  $T'_L$  and  $s_R$  elements from  $T'_R$ , and so with  $s_L + s_R = s$  more elements.

Before considering statement (ii), we consider the following relabelling  $p_+$  of  $T'$ : every real feature in  $feat(b_R)$  is assigned to a feature with its label at node  $b_R$  and every other feature is assigned to itself. The real DT  $T'_L$  can be obtained from  $T'$  by the application of the composition  $r \circ p_* \circ p_+$ .

Now we consider statement (ii). We show that given an example  $e \in exam(b_L)$ ,  $e$  is correctly classified by  $T'$  and to do so we show that  $e$  ends in a leaf of  $T'$  that corresponds to the leaf where  $e$  ends in  $T'_L$ . Say that  $e$  goes along a path  $P$  of  $T'_L$  from the root to a leaf  $\ell$  and let  $Q$  be the corresponding path in  $T'$ , i.e. the path from  $r$  to  $\ell$  (note that by construction  $\ell$  is present in  $T'$  and is still a leaf). Let  $v$  be a node of  $Q$ , we can have the following different cases.

- $v$  is a real feature from  $feat(b_L)$ :  $v$  is also present in  $T'_L$  as real feature;
- $v$  is a real feature from  $feat(b_R)$ :  $v$  might not be present in  $T'_L$  due reductions but if it is present it is a future feature  $A_i$  for some  $i \in [k]$ ;
- $v$  is a future feature  $f_A$ :  $v$  might not be present in  $T'_L$  due reductions but if it is present it is still the same future feature  $A_i$ .

If  $v$  is present in  $T'_L$  then the behaviour of  $v$  on  $e$  in  $T'_L$  and in  $T'$  is the same. Suppose now  $v$  is a node of  $Q$  that is being reduced due his label and so it is not present in  $T'_L$ . This means there is a set of ancestors of  $v$  such that their labels allows to remove  $v$  and by construction  $v$  behaves on  $e$  like those ancestors. This proves  $e$  goes along  $Q$  and in particular it ends at leaf  $\ell$  and so  $T'$  is a real DT for  $b_L$ . With symmetric construction, we show that  $T'$  is also a real DT for  $b_R$ .

Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ . In particular, we recall that  $T'$  is a real DT for  $b$  with actual feature labels in  $[k] \cup [k']$  and future feature labels in  $\mathcal{P}([k])$ .

We create at real DT  $T'_L$  by the application of the composition  $r \circ p_* \circ p_+$  to  $T'$ . By assumption  $T'$  is a real DT for  $b_L$  and by construction  $T'_L$  is a real DT for  $b_L$ . Denote with  $T_L$  the DT template obtained from  $T'_L$  by standard reduction and denote with  $s_L$  the number of nodes that have been deleted from  $T'_L$  to obtain  $T$ . By induction we have  $(T_L, s_L) \in \mathcal{R}(b_L)$ . Now we note that  $T_L$  is obtained from  $T$  after the application of the composition  $r \circ p_*$ . In a symmetric way, we construct  $T'_R, T_R$  and the record  $(T_R, s_R) \in \mathcal{R}(b_R)$ . Then  $(T, s_L + s_R) \in \mathcal{R}(b)$ . ◀

« « « < HEAD

► **Lemma 14** (relabel node). *Let  $b \in V(B)$  be relabel node. Then  $\mathcal{R}(b)$  can be computed in time  $\mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$ .*

**Proof.** Let  $b_C$  be the unique child of  $b$  in  $B$ . Let  $R$  be the mapping of  $[k]$  to itself that represent the node  $b$ . Moreover, since we are considering a *nice* NLC-expression we can assume  $R$  is the identity mapping, i.e.  $R(\ell) = \ell$ , for all values except for a unique element  $i$  of its domain, i.e.  $R(i) = j$  for some  $j \in [k] \setminus \{i\}$ .

We say that a future feature  $A$  is *good* if it does not distinguish between  $i$  and  $j$ , that is  $i \in A$  if and only if  $j \in A$ , and *bad* otherwise. Let  $(T_C, s_C)$  be an element of  $\mathcal{R}(b_C)$ . Let  $p''$  the following relabelling of the DT template  $T_C$ : every feature with label  $i$  is assigned to label  $j$  and every future feature with label  $A$  is assigned to the future feature with label  $A \setminus \{i\}$ .

580 If  $T_C$  has a bad future feature then we do not take any other action. Suppose now  $T_C$   
 581 has only good future features; now let  $T$  be the DT template obtained from  $T_C$  after the  
 582 application of the composition  $r \circ p''$  and let  $s^*$  be the number of nodes that have been  
 583 deleted from  $T_C$  to  $T$ .

584 If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s' \leq s_C + s^*$  then we do  
 585 not take any other action. If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  
 586  $s' > s_C + s^*$  then we replace it with  $(T, s_C + s^*)$ . If there is no record in  $\mathcal{R}(b)$  of the form  
 587  $(T, s')$  for some integer  $s'$  then we add  $(T, s_C + s^*)$  to  $\mathcal{R}(b)$ .

588 Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Consider record  $(T_C, s_C)$   
 589 in  $\mathcal{R}(b_C)$ . In  $\mathcal{O}(k)$  time we check if  $T_C$  all the future features are good. For every such DT  
 590  $T_C$ , there are at most  $2^{2k}$  paths from the root to the leaves and for every of these paths there  
 591 are at most  $k$  nodes for each of the following: feature with label  $i$  and and future feature  
 592 that contains  $i$ . This means  $r \circ p''$  can be done in  $\mathcal{O}(k)$  time. This means to compute  $\mathcal{R}(b)$   
 593 takes  $\mathcal{O}(k|\mathcal{R}(b_C)|) = \mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$  time.

594 Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if  
 595 and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$   
 596 of  $T$  for  $b$ .

597 We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exists a  
 598 record  $(T_C, s_C) \in \mathcal{R}(b_C)$  such that  $T$  is obtained from  $T_C$  after the application of  $r \circ p''$  and  
 599 let  $s^* = s - s_C$ . By induction  $s_C$  is the minimum amount of nodes that have been deleted  
 600 from a witness  $T'_C$  of  $T_C$  for  $b_C$ . By construction we also know that every future feature of  
 601 both  $T'_C$  and  $T_C$  is good.

602 Denote with  $T'$  the real DT obtained  $T'_C$  after the application of  $r \circ p''$ : note that this  
 603 last reduction does not any node since every future feature of  $T'_C$  is good and there is no  
 604 feature with label  $i$ . To conclude this part of the proof we have to show two things: (i)  $T$  is  
 605 obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a witness of  $T$  for  $b$ .

606 Before proving (i), we describe how  $T$  can be obtained from  $T'$ . Let  $p'''$  be the following  
 607 relabelling of  $T'$ : every real feature that contains  $j$  is assigned to the real feature  $A \cup \{i\}$   
 608 and every other feature is assigned to itself. Then the application of the composition  $p'''$ ,  
 609 the standard reduction and  $r \circ p''$  to  $T'$  is exactly the standard reduction for  $T'$  which then  
 610 result to the DT template  $T$ . By Lemma 15 the score of the standard reduction from  $T'$  to  
 611  $T$  is exactly  $s_C + s^* = s$ .

612 Now we consider statement (ii). First note that  $exam(b) = exam(b_C)$ . We show that  
 613 a given example  $e \in exam(b)$  is correctly classified by  $T'$ . Say that  $e$  goes along a path  $P$   
 614 of  $T'_C$  from the root to a leaf  $\ell$ . We show  $e$  goes along the path  $P$  in  $T'$  as well: every real  
 615 feature has not changed and so  $e$  behaves the same. Since every future feature of  $T'_C$  is good,  
 616 then  $e$  behave the same on the corresponding future feature of  $T'$ .

617 Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum  
 618 number of elements that have been deleted from a witness  $T'$  of  $B$  for  $b$ . In particular, we  
 619 recall that real  $T'$  is a DT for  $b$  with real features and future feature labels in  $\mathcal{P}([k] \setminus \{i\})$ .

620 We create the real DT  $T'_C$  as the application of  $r \circ p'''$  to  $T'$ , the DT template  $T_C$  as the  
 621 application of the standard reduction to  $T'_C$ . By construction we have  $(T_C, s_C) \in \mathcal{R}(b_C)$ ,  
 622 where  $s_C$  is the number of nodes that have been removed from  $T'_C$  to  $T_C$ . Note that  $T_C$  has  
 623 only good future features. Finally we note that  $T$  is obtained from  $T_C$  by the application of  
 624  $r \circ p''$ . ◀

3.4 Formal Definition of Records and Preliminary Results

=====

## 627 NLC-width

628 » » » > e150fdde332112fd1c2acb6bd85a9a5606b79547 We start off with some definitions. We  
 629 say an edge is a *left (right) edge* of a subcubic rooted tree if it connects a non-leaf node with  
 630 his left (resp. right) child. Let  $Y$  be a rooted subcubic tree and  $S \in \{left, right\}$ , then we  
 631 say the pair  $(Y, S)$  is a *single pair* if the root of  $Y$  has at most one child and the side  $S$   
 632 indicates whether the edge from the root is either a left or right edge. Moreover, we say that  
 633  $(Y, S)$  is single pair in a subcubic rooted tree  $T$  if  $Y$  is a maximal subtree of  $T$  and in  $Y$  the  
 634 root have at most the  $S$  child. Note that when tree of a single pair is made of just a node,  
 635 the side is not relevant.

636 Now we can define two operations on subcubic rooted trees and single pairs. We say that  
 637 we *plug in* a single pair  $(Y, S)$  in a left (right) edge  $uv$  as follows: we make the root  $y$  of  $Y$  the  
 638 left (right) child of  $u$ ,  $Y \setminus \{y\}$  to be the  $S$  subtree of  $y$  and  $v$  to be the  $H \in \{left, right\} \setminus S$   
 639 child of  $y$ . See Figure 3 for the corresponding drawings. Note after a plug in of a single pair  
 640 in an edge, the node  $v$  belongs in the same side of the subtree rooted at  $u$  as it was before  
 641 the plug in.

■ **Figure 3** The drawings describe the plug in operation in the different four cases. The bold part highlight the single pair  $(Y, S)$ .

642 Let  $(Y, S)$  be a single pair in a rooted subcubic tree  $T$ , then we *remove*  $(Y, S)$  from  $T$  as  
 643 follows. Let  $y$  be the root of  $Y$ . If  $y$  is the root of  $T$ , then we obtain an empty tree. If  $y$  is a  
 644 leaf node of  $T$ , then we obtain  $T - y$ . Otherwise let  $y$  be a non-root and non-leaf node, let  $u$   
 645 be the parent of  $y$  and  $v$  be the child of  $y$  that is not in  $V(Y)$ , then we consider the tree  
 646 obtained from  $T$  after replacing  $y$  with  $v$  as the child of  $u$  and deleting  $Y$ . See Figure 4 for  
 647 an example.

■ **Figure 4** The drawing describe an example of the remove operation: a single pair  $(Y, right)$  is removed from a subcubic rooted tree. The bold part highlight the single pair  $(Y, S)$ .

648 It is clear from the four different plug in cases that if we want to plug in two pairs  $(Y, S)$   
 649 and  $(Y', S')$  on an edge  $uv$  such that the ancestor-descendant relationship is given, say  $y$  of  
 650  $Y$  has to be in the path from the root to  $y'$  of  $Y'$ , then we can do these plug ins in any order  
 651 but with some care. It is the same if we first plug in  $(Y, S)$  in the edge  $uv$  and then plug in  
 652  $(Y', S')$  in the edge  $yv$  or if we first plug in  $(Y', S')$  in the edge  $uv$  and then plug in  $(Y, S)$  in  
 653 the edge  $uy'$ . See Figure 5 for the an example.

■ **Figure 5** An example of plugging in two pairs  $(Y, \text{left})$  and  $(Y', \text{right})$  in a left edge  $uv$ .

For a subset of labels  $A \subseteq [k]$ , we define the feature template  $f_A$  by setting  $e(f_A) = 1$  if and only if  $\text{lab}(e) \in A$  and  $e(f_A) = 0$  otherwise. With a small abuse of notation, we often identify the feature template  $f_A$  with the corresponding subset of labels  $A$ .

Suppose we have a DT such that some feature label  $i$  occurs twice on a path from the root to the leaves, say  $f_1$  is the instance closer to the root and  $f_2$  is the other instance. If  $f_2$  is in the left (resp. right) subtree of  $f_1$ , we remove  $f_2$ 's right (resp. left) subtree. In this case we say we have done an *actual removal*.

Suppose we have a feature template labelled  $A$  in our decision tree. Let  $A_1, \dots, A_\ell$  be the sequence of feature templates on the path from the root to  $A$  in order (not including  $A$ ). Let  $A'_i = A_i$  if  $A$  is in the right sub-tree of  $A_i$  and let  $A'_i = \overline{A_i}$  otherwise. If  $\overline{A} \subseteq A'_1 \cup \dots \cup A'_\ell$ , then we remove the subtree rooted at the left child of  $A$ . If  $A \subseteq \overline{A'_1} \cup \dots \cup \overline{A'_\ell}$ , then we remove the subtree rooted at the right child of  $A$ . In this case we say we have done a *template removal*. If this procedure has been applied to a record exhaustively, we say that the DT is *reduced*.

To be short, for a DT  $T$  and a node  $v$ , we write  $v \in T$  instead of  $v \in V(T)$  and  $v \notin T$  otherwise. In a DT  $T$  we say that path  $p$  is a *downward* path if it is contained in a path having the root as endpoint.

We now formally define two important operations. Given a DT  $T$ , we say that we *reduce*  $T$  if we exhaustively do actual removals and template removals. Call  $r(T)$  the resulting DT.

Recall that in any DT  $T$ , every non-leaf node  $v$  has one of the following three contents:  $v$  is a real feature (without label), or  $v$  is a feature with a label, or  $v$  is a future feature with the corresponding subset of labels. A *relabelling*  $p$  for  $T$  is an assignment of contents of  $T$  as follows. Every feature is assigned to a feature with is either future, real or with a label. We say that we *relabel* the DT  $T$  via the relabelling  $p$  if for every node of  $T$  we apply the corresponding assignment and call  $p(T)$  the resulting DT.

The following lemma shows that, after repeatedly applying it the necessary amount of times, to obtain a reduced DT after a sequence of relabels, it is safe to reduce at the end.

► **Lemma 15 (Relabelling Lemma).** *Let  $T$  be a DT and  $p$  be relabelling of  $T$ . Then  $(r \circ p \circ r)(T) = (r \circ p)(T)$ .*

**Proof.** For every  $v \in T$ , we want to prove  $v \in (r \circ p \circ r)(T) \Leftrightarrow v \in (r \circ p)(T)$ .

$\Rightarrow$  Suppose there is a node  $v \notin (r \circ p)(T)$ . Since  $v \in p(T)$ , there is a set of ancestors of  $v$  in  $p(T)$  that allows to remove  $v$ . Let  $A_v$  be the union of all the minimal set of ancestors of  $v$  in  $p(T)$  that allows to remove  $v$ . If  $A_v$  is a set of ancestors of  $v$  in  $T$  that allows to reduce  $v$

then  $v \notin r(T)$  and so  $v \notin (r \circ p \circ r)(T)$ . Otherwise let  $A'_v$  be the subset of  $A_v$  in  $(p \circ r)(T)$ . We conclude by noting that  $A'_v$  contains one of the minimal sets  $A_v$  is composed of and so  $v \notin (r \circ p \circ r)(T)$ .

⇐ Suppose there is a node  $v \notin (r \circ p \circ r)(T)$ . If  $v \in (p \circ r)(T)$ , there exists a set  $A_v$  of ancestors of  $v$  in  $(p \circ r)(T)$  that allows to reduce  $v$ . Then  $A_v$  is a set of ancestors of  $v$  in  $p(T)$  that allows to reduce  $v$  and so  $v \notin (r \circ p)(T)$ . If  $v \notin (p \circ r)(T)$  then  $v \notin r(T)$ : there exists a set  $A_v$  of ancestors of  $v$  in  $T$  that allows to remove  $v$ . This means  $A_v$  is a set of ancestors of  $v$  in  $p(T)$  that allows to remove  $v$  and so  $v \notin (r \circ p)(T)$ . ◀

We say that a DT  $T$  is a *real DT* if every non-leaf node is either a real feature or a future feature, whereas it is a *DT template* if it contains no real feature.

Let  $B$  be a rooted subcubic tree that corresponds to a  $k$ -NLC expression of the graph  $G_I(E)$ . For  $b \in V(B)$ , we write  $feat(b)$  and  $exam(b)$  for the sets of features and examples introduced at node  $b$ . We say that a real DT  $T$  is a DT for the node  $b$  if every real feature of  $T$  is an element of  $feat(b)$  and every example in  $exam(b)$  is correctly classified by  $T$ , i.e. if  $e \in exam(b) \cap E^+$  then  $e$  ends in a leaf with a  $+$  label and if  $e \in exam(b) \cap E^-$  then  $e$  ends in a leaf with a  $-$  label.

Given a real DT  $T$  and a node  $b \in B$ , often we want to perform a very specific composition of operations. Let  $p_b$  be the following relabelling of  $T$ : every real feature of  $T$  is assigned to a feature with the label given by the  $k$ -NLC expression at node  $b$  and every other feature is assigned to itself. Then the composition  $r \circ p_b$  is called the *standard reduction* of  $T$  at node  $b$ . Given a DT  $T$  and a node  $b \in B$ , it is useful to give the following relabelling  $p'_b$ : every feature with a label is assigned to the real feature of that node. The relabelling  $p'_b$  is called the *real relabelling* of  $T$  at node  $b$ .

We say that a DT template  $T$  is a DT for the node  $b$  if there exists a real DT  $T'$  for  $b$  such that  $T$  is the standard reduction of  $T'$ . In this case we say that  $T'$  is the witness of  $T$  for  $b$ .

► **Lemma 16.** *If there are  $\ell$  features with labels and  $2^h$  future features, then every reduced DT template has height at most  $\ell + h$ . Furthermore, every path from the root to the leaves contains at most  $\ell$  features with label and at most  $h - 1$  future features.*

**Proof.** Consider a path  $P$  of maximum length from the root to the leaves in a reduced DT template  $T$ . By the assumptions on  $T$ , no feature with label appears more than once on this path: the number of these feature nodes on this path is at most  $\ell$ . Consider two future features  $f_A$  and  $f_{A'}$  that appear in  $P$ , say  $f_A$  is the instance closer to the root. Since  $T$  is reduced, we must have that  $\emptyset \subset A' \subset A$ . Since the label of any future feature has at most  $h$  elements, there can be at most  $h - 1$  feature template nodes on this path. The path ends with a leaf node, so this gives a total of  $\ell + h - 1 + 1 = \ell + h$  nodes, as required. ◀

► **Lemma 17.** *If there are  $\ell$  features with label and  $2^h$  future features, then there are at most  $(\ell + 2^k + 2)2^{\ell+k+1}$  reduced DT templates. Furthermore, these can be enumerated in  $\mathcal{O}((\ell + 2^k + 2)2^{\ell+k+1})$ -time.*

**Proof.** By Lemma 16, the tree has height at most  $\ell + k$ . Each node of the decision tree could be a feature with label, a future feature, or a leaf: at most  $\ell + 2^h + 2$  different contents. Since there are at most  $2^{\ell+h+1}$  nodes in the tree, there are at most  $(\ell + 2^h + 2)2^{\ell+h+1}$  possible decision trees. ◀

The *semantics* for a record are defined as follows. We say that a pair  $(T, s)$  is a *record* for the node  $b \in B$  and we write  $(T, s) \in \mathcal{R}(b)$ , if  $T$  is a DT template for  $b$  and  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ .

### 3.5 Proof to the Main Result

Now, it suffices to compute  $\mathcal{R}(b)$  via leaf-to-root dynamic programming. The following four lemmas show how this can be achieved for all of the four types of nodes in a  $k$ -NLC expression tree  $B$ .

► **Lemma 18** (leaf node). *Let  $b \in V(B)$  be a leaf node. Then  $\mathcal{R}(b)$  can be computed in time  $\mathcal{O}(k(2^k + 3)2^{k+2})$ .*

**Proof.** Let  $v$  be the vertex of  $G_I(E)$  that corresponds to the leaf node  $b$ . This means either  $v \in E$  or  $v \in feat(E)$ .

We have to enumerate all possible reduced DT templates  $T$  for  $b$ . It is enough to consider all reduced DT templates  $T$  of height at most  $k + 1$  and discard those that are not DT templates for  $b$ ; these can be enumerated in time  $\mathcal{O}((2^k + 3)2^{k+2})$  by Lemma 17 and the check can be done in time  $\mathcal{O}(k)$ . We add the pair  $(T, 0)$  to the set of records  $\mathcal{R}(b)$ .

Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ .

We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction, we have that  $s = 0$  and  $T$  is a DT template for  $b$  which is already reduced. Then  $T$  is trivially a witness of  $T$  for  $b$ .

Now we prove the backward direction. Let  $T$  be a reduced DT template such that 0 is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ . This means  $T'$  is obtained from  $T$  after the real relabelling at node  $b$  is applied:  $T$  is a DT template among the considered DTs above which leads to the fact that  $(T, 0) \in \mathcal{R}(b)$ . ◀

► **Lemma 19** (join node). *Let  $b \in V(B)$  be a join node. Then  $\mathcal{R}(b)$  can be computed in time  $\mathcal{O}(k(2k + 2^k + 2)2^{6k+1})$ .*

**Proof.** Let  $b_L$  and  $b_R$  be the left, resp. right, child of  $b$  in  $B$ : we may assume the labels for  $feat(b_L)$  are in  $[k]$  and the labels for  $feat(b_R)$  are in  $[k']$ . Moreover, let  $M$  be the  $k \times k$   $\{0, 1\}$  matrix that represent the node  $b$ . Finally, for every label  $i \in [k]$ , let  $A_i = \{j \in [k] \mid M_{i,j} = 1\}$ .

We consider every reduced DT  $T$  for  $b$  with feature labels in  $[k] \cup [k']$  and future feature labels in  $\mathcal{P}([k])$ ; these can be enumerated in time  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$  by Lemma 17.

For every such DT  $T$ , we create a DT  $T_L$  as follows. Let  $p_*$  be the following relabelling: for every  $i' \in [k']$ , every feature with label  $i'$  is assigned to the future feature  $A_i$ . Then we apply the composition  $r \circ p_*$  to  $T$ . In a symmetrical way we create a DT  $T_R$ . Let  $p'_*$  be the following relabelling: for every  $i \in [k]$ , every feature with label  $i$  is assigned to the future feature  $A_{i'}$  and every future feature  $A_i$  is assigned to the future feature  $A_{i'}$ . Then we apply the composition  $r \circ p'_*$  to  $T$ .

Now we want to understand if there is a record in  $\mathcal{R}(b_L)$  of the form  $(T_L, s_L)$  for some positive integer  $s_L$  and if there is a record in  $\mathcal{R}(b_R)$  of the form  $(T_R, s_R)$  for some positive integer  $s_R$ : if the answer is yes in both cases, we add a record  $(T, s_L + s_R)$  to  $\mathcal{R}(b)$ ; otherwise we discard this option.

Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Every reduced DT  $T$  can be enumerated in time  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$  by Lemma 17. For every such DT  $T$ , there are at most  $2^{3k}$  paths from the root to the leaves and for every of these paths there are at most  $k$  nodes for each of the following: features with label in  $[k]$ , features with label in  $[k']$  and future features by Lemma 16. This means  $r \circ p_*$  and  $r \circ p'_*$  can be done in  $\mathcal{O}(k2^{3k})$  time.

Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ . We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exist records  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$  such that  $T_L$  and  $T_R$  are obtained by the application of  $r \circ p_*$  and  $r \circ p'_*$  respectively to  $T$  and  $s_L + s_R = s$ .

By induction, for  $H \in \{L, R\}$ , we know that  $s_H$  is the minimum number of elements that have been deleted from a witness  $T'_H$  of  $T_H$  for  $b_H$ .

For  $H \in \{L, R\}$ , we define maps  $x_H$  and  $y_H$  as follows. Let  $x_H : V(T_H) \rightarrow V(T)$  and  $y_H : V(T_H) \rightarrow V(T'_L)$  be the functions that maps every node of  $T_H$  to the corresponding node in  $T$  and in  $T'_L$  and note that by constructions both these maps are injective.

Moreover,  $V(T) \setminus \text{Im}(x_H)$  and  $V(T'_H) \setminus \text{Im}(y_H)$  can be partitioned into subtrees that have been deleted after the application of  $r \circ p_*$ ,  $r \circ p'_*$  on  $T$  or of the standard reduction on  $T'_H$ : let  $X_H^*$  and  $Y_H^*$  be the set of roots of the above subtrees in  $V(T) \setminus \text{Im}(x_H)$  and  $V(T'_H) \setminus \text{Im}(y_H)$  respectively. In addition, for every element  $y \in Y_H^*$ , let  $Y_y^H$  be the maximal subtree of  $T'_H$  rooted at  $y$  with no elements from  $\text{Im}(y_H)$  and that does not contain any vertex from  $Y_H^* \setminus \{y\}$ ; let  $(Y_y^H, S_y^H)$  the corresponding single pair. «««< HEAD ===== »»»> e150fdde332112fd1c2acb6bd85a9a5606b79547 In a similar way, for every element  $x \in X_H^*$ , let  $X_x^H$  be the maximal subtree of  $T$  rooted at  $x$  with no elements from  $\text{Im}(x_H)$  and that does not contain any vertex from  $X_H^* \setminus \{x\}$ ; let  $(X_x^H, S_x^H)$  the corresponding single pair. Finally, for every  $y \in Y_H^*$ , let  $P_y^H$  be the shortest downwards path in  $T'_H$  that contains  $y$  and with both endpoints in  $\text{Im}(y_H)$ , say  $y_H(t)$  and  $y_H(t')$ .

*Claim 1: For every  $H \in \{L, R\}$  and for every  $y, y' \in Y_H^*$ , the paths  $P_y^H$  and  $P_{y'}^H$  are either edge disjoint or  $P_y^H = P_{y'}^H$ .*

*Proof.* If  $P_y^H$  and  $P_{y'}^H$  are edge disjoint, then the statement is proven immediately. Suppose  $P_y^H$  and  $P_{y'}^H$  share an edge. By minimality and the fact they are downwards paths,  $P_y^H$  and  $P_{y'}^H$  share the endpoint towards the root. If they also share the other endpoint, then the statement is proven immediately. Suppose now their endpoints towards the leaves is different, say  $w$  and  $w'$ , and consider the last edge those paths have in common in a root-to-leaf order, say  $uv$ .

Without loss of generality, we can assume  $w$  belongs to the left branch of  $v$  and  $w'$  belongs to the right branch of  $v$ . Note that  $v \in V(T'_H) \setminus \text{Im}(y_H)$ , or we get a contradiction due the minimality of  $P_y^H$ . Now we get the following contradiction: by construction,  $w$  and  $w'$  are both elements of  $\text{Im}(y_H)$  but at least one of them must be in  $V(T'_H) \setminus \text{Im}(y_H)$  since it is an element of either  $Y_y^H$  or of  $Y_{y'}^H$ . This proves Claim 1.

Now for every  $y \in Y_H^*$  we consider the path  $Q_y^H$  in  $T$  having endpoints  $x_H(t)$  and  $x_H(t')$ .

«««< HEAD ===== *Claim 2: For every  $H \in \{L, R\}$  and for every  $y \in Y_H^*$ , every internal vertex of  $Q_y^H$  is an element of  $X_H^*$ .*

*Proof.* Suppose that  $Q_y^H$  has an internal vertex  $t \notin X_H^*$ . By definition, there exists a vertex  $v \in V(T_H)$  such that  $x_H(v) = t$ . Since  $x_H$  is injective then  $v \notin \{v_1, v_2\}$ . Since  $y_H$  is injective  $y_H(v) \notin \{y_H(v_1), y_H(v_2)\}$  and belongs to  $P_y^H$ , which contradicts the minimality of  $P_y^H$ . This proves Claim 2.

Before we describe how to obtain a witness  $T'$  of  $T$  for  $b$ , we must make an observation. We note that  $Im(x_L) \cup Im(x_R) = V(T)$ : the idea is that every node of  $T$  must originate from either  $T_L$  or  $T_R$ .

»»»> e150fdde332112fd1c2acb6bd85a9a5606b79547 Now we are able to describe how to obtain a witness  $T'$  of  $T$  for  $b$ . For every  $y \in Y_L^*$ , in the last edge of path  $Q_y^L$  we plug in the single pair  $(Y_{y'}^L, S_{y'}^L)$  rooted at  $y'$ , for every internal node  $y'$  of  $P_y^L$ , in the order the nodes  $y'$  appear in  $P_y^L$ . Note that, in the case an element of  $Y_L^*$  is present in more than one  $P_y^L$ , we plug in the corresponding single pair only once. Note also that whenever we plug in some single pair  $(Y_{y'}^L, S_{y'}^L)$  in a DT, the tree  $Y_{y'}^L$  has real features and future features as nodes. Call this graph  $T^*$ . Now we do the same sequence of plug ins of the single pairs corresponding to the internal vertices of  $P_y^R$  in the last edge of the path  $Q_y^R$ . Again, in the case an element of  $Y_R^*$  is present in more than one  $P_y^R$ , we plug in the corresponding single pair only once. Call the tree obtained in this way  $T'$ . Note that  $T'$  contains real features from  $feat(b_L)$  and from  $feat(b_R)$  and future features with labels in  $\mathcal{P}([k])$ .

To conclude this part of the proof we have to show two things: (i)  $T$  is obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a real DT for  $b$ . We start proving (i): by construction  $T'$  is obtained from  $T$  after adding  $s_L$  elements from  $T'_L$  and  $s_R$  elements from  $T'_R$ , and so with  $s_L + s_R = s$  more elements.

Before considering statement (ii), we consider the following relabelling  $p_+$  of  $T'$ : every real feature in  $feat(b_R)$  is assigned to a feature with its label at node  $b_R$  and every other feature is assigned to itself. The real DT  $T'_L$  can be obtained from  $T'$  by the application of the composition  $r \circ p_* \circ p_+$ .

Now we consider statement (ii). We show that given an example  $e \in exam(b_L)$ ,  $e$  is correctly classified by  $T'$  and to do so we show that  $e$  ends in a leaf of  $T'$  that corresponds to the leaf where  $e$  ends in  $T'_L$ . Say that  $e$  goes along a path  $P$  of  $T'_L$  from the root to a leaf  $\ell$  and let  $Q$  be the corresponding path in  $T'$ , i.e. the path from  $r$  to  $\ell$  (note that by construction  $\ell$  is present in  $T'$  and is still a leaf). Let  $v$  be a node of  $Q$ , we can have the following different cases.

- $v$  is a real feature from  $feat(b_L)$ :  $v$  is also present in  $T'_L$  as real feature;
- $v$  is a real feature from  $feat(b_R)$ :  $v$  might not be present in  $T'_L$  due reductions but if it is present it is a future feature  $A_i$  for some  $i \in [k]$ ;
- $v$  is a future feature  $f_A$ :  $v$  might not be present in  $T'_L$  due reductions but if it is present it is still the same future feature  $A_i$ .

If  $v$  is present in  $T'_L$  then the behaviour of  $v$  on  $e$  in  $T'_L$  and in  $T'$  is the same. Suppose now  $v$  is a node of  $Q$  that is being reduced due his label and so it is not present in  $T'_L$ . This means there is a set of ancestors of  $v$  such that their labels allows to remove  $v$  and by construction  $v$  behaves on  $e$  like those ancestors. This proves  $e$  goes along  $Q$  and in particular it ends at leaf  $\ell$  and so  $T'$  is a real DT for  $b_L$ . With symmetric construction, we show that  $T'$  is also a real DT for  $b_R$ .

Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ . In particular, we recall that  $T'$  is a real DT for  $b$  with actual feature labels in  $[k] \cup [k']$  and future feature labels in  $\mathcal{P}([k])$ .

We create at real DT  $T'_L$  by the application of the composition  $r \circ p_* \circ p_+$  to  $T'$ . By assumption  $T'$  is a real DT for  $b_L$  and by construction  $T'_L$  is a real DT for  $b_L$ . Denote with  $T_L$  the DT template obtained from  $T'_L$  by standard reduction and denote with  $s_L$

the number of nodes that have been deleted from  $T'_L$  to obtain  $T$ . By induction we have  $(T_L, s_L) \in \mathcal{R}(b_L)$ . Now we note that  $T_L$  is obtained from  $T$  after the application of the composition  $r \circ p_*$ . In a symmetric way, we construct  $T'_R, T_R$  and the record  $(T_R, s_R) \in \mathcal{R}(b_R)$ . Then  $(T, s_L + s_R) \in \mathcal{R}(b)$ .  $\blacktriangleleft$

► **Lemma 20** (relabel node). *Let  $b \in V(B)$  be relabel node. Then  $\mathcal{R}(b)$  can be computed in time  $\mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$ .*

**Proof.** Let  $b_C$  be the unique child of  $b$  in  $B$ . Let  $R$  be the mapping of  $[k]$  to itself that represent the node  $b$ . Moreover, since we are considering a *nice* NLC-expression we can assume  $R$  is the identity mapping, i.e.  $R(\ell) = \ell$ , for all values except for a unique element  $i$  of its domain, i.e.  $R(i) = j$  for some  $j \in [k] \setminus \{i\}$ .

We say that a future feature  $A$  is *good* if it does not distinguish between  $i$  and  $j$ , that is  $i \in A$  if and only if  $j \in A$ , and *bad* otherwise. Let  $(T_C, s_C)$  be an element of  $\mathcal{R}(b_C)$ . Let  $p''$  the following relabelling of the DT template  $T_C$ : every feature with label  $i$  is assigned to label  $j$  and every future feature with label  $A$  is assigned to the future feature with label  $A \setminus \{i\}$ .

If  $T_C$  has a bad future feature then we do not take any other action. Suppose now  $T_C$  has only good future features; now let  $T$  be the DT template obtained from  $T_C$  after the application of the composition  $r \circ p''$  and let  $s^*$  be the number of nodes that have been deleted from  $T_C$  to  $T$ .

If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s' \leq s_C + s^*$  then we do not take any other action. If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s' > s_C + s^*$  then we replace it with  $(T, s_C + s^*)$ . If there is no record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s'$  then we add  $(T, s_C + s^*)$  to  $\mathcal{R}(b)$ .

Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Consider record  $(T_C, s_C)$  in  $\mathcal{R}(b_C)$ . In  $\mathcal{O}(k)$  time we check if  $T_C$  all the future features are good. For every such DT  $T_C$ , there are at most  $2^{2k}$  paths from the root to the leaves and for every of these paths there are at most  $k$  nodes for each of the following: feature with label  $i$  and and future feature that contains  $i$ . This means  $r \circ p''$  can be done in  $\mathcal{O}(k)$  time. This means to compute  $\mathcal{R}(b)$  takes  $\mathcal{O}(k|\mathcal{R}(b_C)|) = \mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$  time.

Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ .

We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exists a record  $(T_C, s_C) \in \mathcal{R}(b_C)$  such that  $T$  is obtained from  $T_C$  after the application of  $r \circ p''$  and let  $s^* = s - s_C$ . By induction  $s_C$  is the minimum amount of nodes that have been deleted from a witness  $T'_C$  of  $T_C$  for  $b_C$ . By construction we also know that every future feature of both  $T'_C$  and  $T_C$  is good.

Denote with  $T'$  the real DT obtained  $T'_C$  after the application of  $r \circ p''$ : note that this last reduction does not any node since every future feature of  $T'_C$  is good and there is no feature with label  $i$ . To conclude this part of the proof we have to show two things: (i)  $T$  is obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a witness of  $T$  for  $b$ .

Before proving (i), we describe how  $T$  can be obtained from  $T'$ . Let  $p'''$  be the following relabelling of  $T'$ : every real feature that contains  $j$  is assigned to the real feature  $A \cup \{i\}$  and every other feature is assigned to itself. Then the application of the composition  $p'''$ , the standard reduction and  $r \circ p''$  to  $T'$  is exactly the standard reduction for  $T'$  which then result to the DT template  $T$ . By Lemma 15 the score of the standard reduction from  $T'$  to  $T$  is exactly  $s_C + s^* = s$ .

Now we consider statement (ii). First note that  $exam(b) = exam(b_C)$ . We show that a given example  $e \in exam(b)$  is correctly classified by  $T'$ . Say that  $e$  goes along a path  $P$  of  $T'_C$  from the root to a leaf  $\ell$ . We show  $e$  goes along the path  $P$  in  $T'$  as well: every real feature has not changed and so  $e$  behaves the same. Since every future feature of  $T'_C$  is good, then  $e$  behave the same on the corresponding future feature of  $T'$ .

Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum number of elements that have been deleted from a witness  $T'$  of  $B$  for  $b$ . In particular, we recall that real  $T'$  is a DT for  $b$  with real features and future feature labels in  $\mathcal{P}([k] \setminus \{i\})$ .

We create the real DT  $T'_C$  as the application of  $r \circ p'''$  to  $T'$ , the DT template  $T_C$  as the application of the standard reduction to  $T'_C$ . By construction we have  $(T_C, s_C) \in \mathcal{R}(b_C)$ , where  $s_C$  is the number of nodes that have been removed from  $T'_C$  to  $T_C$ . Note that  $T_C$  has only good future features. Finally we note that  $T$  is obtained from  $T_C$  by the application of  $r \circ p''$ . ◀

Now we can finally prove Theorem 4 and Theorem ??, which we restate here.

**Theorem 4 (restated).** *Let  $E$  be a CI, let  $(B, \chi)$  be an NLC-expression decomposition of width  $k$  for  $G_I(E)$ , and let  $s$  be an integer. Then, deciding whether  $E$  has a DT of size at most  $s$  is fixed-parameter tractable parameterized by  $k$ . In particular, such computation takes  $\mathcal{O}()$  time.*

**Proof.** We start off by computing  $\mathcal{R}(b)$  for every node  $b$  of  $B$ , via leaf-to-root dynamic programming. An upper bound for the running time for this step is the number of nodes of  $B$  times the maximum running time to compute the record at each node which is given by Lemmas 18, 19 and 20.

Now we look at the root node  $r$  of  $B$ . We go through all the records of  $\mathcal{R}(r)$  and select a record  $(T, s) \in \mathcal{R}(r)$  such that  $|T| + s$  is minimum over all DTs with no future feature. ◀

**Theorem ?? (restated).** *DTS is fixed-parameter tractable parameterized by NLC-width.*

#### 4 An FPT-Algorithm for bounded solution size and $\delta_{max}$ .

In the following, let  $E$  be a CI and  $q \notin feat(E)$ . A *pattern* is a pair  $(T, \varphi)$  where  $T = (V(T), A(T))$  is a rooted subcubic tree, every leaf-node is either a *positive* or *negative* leaf and  $\varphi$  maps every inner-node  $v \in V(T)$  to an element of  $feat(E) \cup \{q\}$ . We say that  $\varphi$  is the *trait* function of  $T$  and  $\varphi(v)$  is the trait of node  $v \in V(T)$ .

A pattern  $(T, \varphi^*)$  is an *improvement* for a pattern  $(T, \varphi)$  if  $\varphi^*(v) = \varphi(v)$  for every  $v$  such that  $\varphi(v) \in feat(E)$ . A *complete improvement*  $(T, \varphi^*)$  for  $(T, \varphi)$  is an improvement such that  $Im(\varphi^*) \subseteq feat(E)$ . Note that any complete improvement of a pattern is a decision tree. Given a pattern  $(T, \varphi)$ , an *threshold assignment* of  $(T, \varphi)$  is a function  $\psi$  that maps every node  $v \in V(T)$  such that  $\varphi(v) \in feat(E)$  to a rational number  $\psi(v)$ .

Given a threshold assignment  $\psi$  for a decision tree  $(T, \varphi)$ , for each node  $v$  of  $T$  we define the set of examples that arrives at node  $v$ ,  $E_T(v)$  as follows:  $E_T(v)$  is the set of all examples  $e \in E$  such that for each left (right, respectively) arc  $(u, w)$  on the unique path from the root of  $T$  to  $v$  we have  $(\varphi(u))(e) \leq \psi(u)$  ( $(\varphi(u))(e) > \psi(u)$ , respectively). A decision tree  $(T, \varphi)$  *correctly classifies* an example  $e \in E$  given  $\psi$  if  $e$  is a positive (negative) example and  $e \in E_T(v)$  for a positive (negative) leaf. We say that  $(T, \varphi)$  *classifies*  $E$  given  $\psi$  if  $T$  correctly classifies every example  $e \in E$  given  $\psi$ .

We say that  $(T, \varphi)$  can classify  $E$  if there exists a complete improvement  $(T, \varphi^*)$  for  $(T, \varphi)$  and there exists a threshold assignment  $\psi$  for  $(T, \varphi^*)$  such that  $(T, \varphi^*)$  classifies  $E$  given  $\psi$ .

## 953 4.1 Preprocess

954 Let  $E$  be a CI, and  $(T, \varphi)$  be a pattern. For every  $v \in V(T)$ , we define the set of *expected*  
955 *examples*  $E_v$  as follows:

- 956 ■ if  $v$  is the root, then  $E_v = E$ ;
- 957 ■ if  $v$  is the left child of a node  $v_p$  such that  $\varphi(v_p) \in \text{feat}(E)$ , then  $E_v = E_{v_p}[\varphi(v_p) \leq$   
958  $\text{th}_L(v_p) + 1]$ ;
- 959 ■ if  $v$  is the right child of a node  $v_p$  such that  $\varphi(v_p) \in \text{feat}(E)$ , then  $E_v = E_{v_p}[\varphi(v_p) >$   
960  $\text{th}_R(v_p) - 1]$ ;
- 961 ■ if  $v$  is a child of a  $v_p$  such that  $\varphi(v_p) = q$ , then  $E_v = E_{v_p}$ .

962 Node that the definition of  $E_v$  is strictly related with the following: if  $\varphi(v) \in \text{feat}(E)$ ,  
963 let  $c_\ell$  and  $c_r$  be the left, resp. right, child of  $v$ , we define two values  $\text{th}_L(v)$  and  $\text{th}_R(v)$  as  
964 follows:

- 965 ■ let  $\text{th}_L(v)$  be the maximum value in  $D_E(\varphi(v))$  such that  $(T_{c_\ell}, \varphi)$  can classify every  
966 example in  $E_v[\varphi(v) \leq \text{th}_L(v)]$ ;
- 967 ■ let  $\text{th}_R(v)$  be the minimum value in  $D_E(\varphi(v))$  such that  $(T_{c_r}, \varphi)$  can classify every example  
968 in  $E_v[\varphi(v) > \text{th}_R(v)]$ .

969 Before formally proving in Lemma 21 that we are able to compute  $E_v$  and  $\text{th}_L(v)$ ,  $\text{th}_R(v)$   
970 (when  $\varphi(v) \in \text{feat}(E)$ ) for every  $v \in V(T)$ , we want to describe the role of  $E_v$  in the proof  
971 of Lemma 22.

972 Let us consider the following situation. Suppose we are trying to find a DT of minimum  
973 size for a CI  $E$  using at least the features in a given support set  $S$ . The first step would be  
974 to compute a minimum size DT  $T^*$  for  $E$  such that  $\text{feat}(T^*) = S$ . Next we analyse the case  
975 an optimal DT for  $E$  uses not only every feature from  $S$  but some additional feature: for this  
976 reason we consider patterns  $(T, \varphi)$  with  $T$  of size at most  $s$  and such that  $S \cup \{q\} = \text{Im}(\varphi)$ .

977 Let us recall a definition. Let  $(T, \varphi)$  be a pattern and  $v \in V(T)$  be an inner node of  
978  $T$  with left child  $\ell$ , right child  $r$ , and parent  $p$ . We say that  $T'$  is obtained from  $T$  after  
979 *left/right-contracting*  $v$  if  $T'$  is a rooted subcubic tree obtained from  $T$  after removing  $v$   
980 together with all nodes in  $T_r/T_\ell$  and adding the edge between  $p$  and  $\ell/r$ ; if  $v$  has no parent  
981 then no edge is added.

982 In order to argue that a pattern  $(T, \varphi)$  can classify  $E$ , we have first to compute a complete  
983 improvement (or a series of improvements that ends up in a complete improvement) of  
984  $(T, \varphi)$ . Let  $v \in V(T)$  such that  $\varphi(v) = q$ . If the pattern  $(T', \varphi)$ , where  $T'$  is obtained after  
985 left/right-contracting  $v$ , can classify every example in  $E_v$ , then we discard the pattern  $(T, \varphi)$ :  
986  $(T', \varphi)$  is equivalent to  $(T, \varphi)$  but of smaller size. TO EXPAND.

987 **Claim 1.** *Let  $(T, \varphi)$  be a pattern. For every node  $v \in V(T)$ ,  $(T_v, \varphi)$  can not classify every*  
988 *example in  $E_v$ .*

989 We prove this claim by induction on the height of  $T$ .

990 Let us first consider the case in which  $v$  is the root of  $T$ . Here we have that  $T_v = T$  and  
991  $E_v = E$  and so the claim directly follows from the assumption that  $T$  can not be extended  
992 to a DT for  $E$ . Now let  $v$  be the child of an unknown feature node  $v_p$ . Recall that, by  
993 assumption,  $v_p$  does not distinguish any pair of examples and so it is safe to assume that  
994  $E_{v_p}$  is a set of examples that can not be classified by extending  $T_v$ .

995 Finally suppose now that  $v$  is the left child of a supported feature node  $v_p$ . By the  
996 maximality of  $\text{th}_L(v_p)$ , the set  $E_v = E_{v_p}[\varphi(v_p) \leq \text{th}_L(v_p) + 1]$  necessarily contains examples  
997 that can not be classified by extending  $T_v$ . In a similar way, the minimality of  $\text{th}_R(v)$  shows

that the claim holds when  $v$  is the right child of a supported feature node. This proves the Claim 1.

Thanks to Claim 1, it follows that for every node  $v$  that has a supported feature,  $th_L(v) < th_R(v)$ . Suppose that for some node  $v$  with supported feature  $f$  we have  $th_L(v) \geq th_R(v)$ . Setting  $(feat(v) = th_L(v))$  generates a DT for  $E_v$ , which is a contradiction.

► **Lemma 21.** *Let  $E$  be a CI, let  $T$  be a partial DT of depth at most  $d$  and let  $\bar{\alpha}$  be a  $S$ -feature assignment of  $T$  for a support set  $S$ . Then there is an algorithm that runs in time  $\mathcal{O}(2^{d^2/2} n^{1+o(1)} \log n)$  and computes the set  $E_v$  and thresholds  $th_L(v)$  and  $th_R(v)$  for every node  $v \in V(T)$ .*

**Proof.** The idea is to use the recursive algorithm **findLR** illustrated in Algorithm 1. That is, given  $E$ ,  $T$ ,  $\bar{\alpha}$ , the algorithm **findLR** attempts to find the triples  $(E_v, th_L(v), th_R(v))$  for every node  $v \in V(T)$ . Lines 3 to 4: if  $T$  consists of a leaf node, the algorithm just report  $(E, \text{nil}, \text{nil})$ . Let  $c_\ell$  and  $c_r$  be the left, resp. right, child of the root  $v$ . Lines 6 to 11: if the root of  $T$  has an unknown feature, the algorithm calls itself recursively to compute the triple for  $(E, T_{c_\ell}, \alpha)$  and  $(E, T_{c_r}, \alpha)$ . Lines 13 to 15: if the root of  $T$  has a supported feature  $f$ , the algorithm computes the pair  $(t_\ell, t_r)$  for the root using the algorithm **binarySearch** and then calls itself recursively to compute the triple for  $(E[f \leq t_\ell + 1], T_{c_\ell}, \alpha)$  and  $(E[f > t_r - 1], T_{c_r}, \alpha)$ .

A key element for the correctness of **findLR** is the algorithm **binarySearch** illustrated in Algorithm 2. Given  $E$ ,  $T$ ,  $\alpha$ ,  $f$ ,  $c_\ell$  and  $c_r$ , this algorithm computes the pair  $(t_\ell, t_r)$  for the root of  $T$ . This sub-routine performs a standard binary search procedure on the array  $D$  containing all the values in  $D_E(f)$  in ascending order to find maximum  $t_\ell$  and minimum  $t_r$  such that  $(T_{c_\ell}, \alpha)$  and  $(T_{c_r}, \alpha)$  can be extended to DT for  $E[f \leq t_\ell]$  and for  $E[f > t_r]$  respectively. To achieve this, the sub-routine makes at most  $\log|E|$  calls to **findTH**; note that each of those calls is made for a tree of smaller depth. Lines 3 to 12: the algorithm finds the maximum  $t_\ell$  by calling algorithm **findTH** in Line 6 repeatedly. Lines 13 to 22: the algorithm finds the minimum  $t_r$  by calling algorithm **findTH** in Line 16 repeatedly.

A sub-routine used for **binarySearch** is the algorithm **findTH** illustrated in Algorithm 3. This algorithm is very similar to Algorithm 1 but the output is some way much simpler.

The running time of Algorithm 1 can now be obtained by multiplying the number of recursive calls to **findLR** with the time required for one recursive call. To obtain the number of recursive calls first note that if **findLR** is called with a pseudo DT of depth  $d$ , then it makes at most  $(2 \log n) + 2$  recursive calls to **findLR** with a pseudo DT of depth at most  $d - 1$ , where  $n = |E|$ . Therefore the number  $T(n, d)$  of recursive calls for a pseudo DT of depth  $d$  is given by the recursion relation  $T(n, d) = (2(\log n) + 2)T(n, d - 1)$  starting with  $T(n, 0) = 0$ . This implies that  $T(n, d) \in \mathcal{O}((\log n)^d)$ . Finally, the runtime for one recursive call is easily seen to be at most  $\mathcal{O}(n \log n)$ . Hence, the total runtime of the algorithm is at most  $\mathcal{O}((\log n)^d n \log n)$ , which because (see also [9, Exercise 3.18]):

$$(\log n)^d \leq 2^{d^2/2} 2^{\log \log d^2/2} = 2^{d^2/2} n^{o(1)}$$

is at most  $\mathcal{O}(2^{d^2/2} n^{1+o(1)} \log n)$ . ◀

## 4.2 The algorithm

Now we have computed a set  $E_v$  for every node  $v \in V(T)$ , whether it is a leaf or has a supported or unknown feature. A *pool set* for node  $v \in V(T)$  is a set  $\Pi(v) \subseteq E_v$ , such that if every example of  $\Pi(v)$  arrives at node  $v$  then either

■ **Algorithm 1** Algorithm to compute the triple  $(E_v, th_L(v), th_R(v))$  for every node  $v \in V(T)$ .

**Input:** CI  $E$ , pseudo DT  $T$ ,  $S$ -feature assignment  $\alpha$  for  $T$

**Output:** a triple  $(E_v, th_L(v), th_R(v))$  for every node  $v \in V(T)$ .

---

```

1: function findLR( $E, T, \alpha$ )
2:    $r \leftarrow$  “root of  $T$ ”
3:   if  $r$  is a leaf then
4:     return ( $E, \text{nil}, \text{nil}$ )
5:    $c_\ell, c_r \leftarrow$  “left child and right child of  $r$ ”
6:   if  $r$  has an unknown feature then
7:      $\lambda_\ell \leftarrow \text{findLR}(E, T_{c_\ell}, \alpha)$ 
8:      $\lambda_r \leftarrow \text{findLR}(E, T_{c_r}, \alpha)$ 
9:     if  $\lambda_\ell \neq \text{nil}$  and  $\lambda_r \neq \text{nil}$  then
10:      return ( $E, \text{nil}, \text{nil}$ )  $\cup \lambda_\ell \cup \lambda_r$ 
11:   return nil
12:    $f \leftarrow \alpha(r)$ 
13:    $(t_\ell, t_r) \leftarrow \text{BINARYSEARCH}(E, T, \alpha, c_\ell, c_r, f)$ 
14:    $\lambda_\ell \leftarrow \text{findLR}(E[f \leq t_\ell + 1], T_{c_\ell}, \alpha)$ 
15:    $\lambda_r \leftarrow \text{findLR}(E[f > t_r - 1], T_{c_r}, \alpha)$ 
16:   return ( $E, t_\ell, t_r$ )  $\cup \lambda_\ell \cup \lambda_r$ 

```

---

- 1042 ■  $T$  can not be extended to a DT for  $E$ , or  
 1043 ■ there is an node  $u \in V(T_v)$  with unknown feature  $f_u$  and two elements  $e, e' \in \Pi(v)$  such  
 1044 that  $f_u$  must distinguish  $e$  and  $e'$ .

1045 For every node  $v \in V(T)$ , we define  $\Pi(v)$  in a leaves-to-root fashion as follows:

- 1046 (a) if  $v$  is a negative leaf then  $\Pi(v) = \{e^+\}$ , where  $e^+$  is any example in  $E^+ \cap E_v$ ;  
 1047 (b) if  $v$  is a positive leaf then  $\Pi(v) = \{e^-\}$ , where  $e^-$  is any example in  $E^- \cap E_v$ ;  
 1048 (c) if  $v$  is a supported feature node. Let  $c_\ell$  and  $c_r$  be the left, resp. right, child of  $v$ , then  
 1049  $\Pi(v) = \Pi(c_\ell) \cup \Pi(c_r)$ ;  
 1050 (d) if  $t$  is an unknown feature node. Let  $c_\ell$  and  $c_r$  be the left, resp. right, child of  $v$ , then  
 1051  $\Pi(v) = \Pi(c_\ell) \cup \Pi(c_r)$ .

1052 Now we want to show that the construction of  $\Pi$  is correct, that is:

1053 **Claim 2.**  $\Pi(v)$  is a pool set for  $v$  for every node  $v \in V(T)$ .

1054 We start proving (a): let  $v$  be a negative leaf and suppose there is an element  $e^+ \in E^+ \cap E_v$ ,  
 1055 then there is no threshold assignment for  $T$  that would correctly classify  $e$ . The correctness  
 1056 for (b) is obtained by a symmetric argument. Let us consider (c) and let  $f \in S$  be the  
 1057 feature at  $v$ : thanks to the preprocessing, for every  $e_\ell \in \Pi(c_\ell)$  and  $e_r \in \Pi(c_r)$ , we know that  
 1058  $f(e_\ell) < f(e_r)$ . This means that either every element of  $\Pi(c_\ell)$  is sent to  $c_\ell$  or every element of  
 1059  $\Pi(c_r)$  is sent to  $c_r$ : by induction the statement is proven. Finally we consider statement (d).  
 1060 If every element of  $\Pi(c_\ell)$  is sent to  $c_\ell$  or every element of  $\Pi(c_r)$  is set to  $c_r$ , the statement  
 1061 is proven by induction. Otherwise, there is an example  $e_\ell \in \Pi(c_\ell)$  that ends in  $c_r$  and an  
 1062 example  $e_r \in \Pi(c_r)$  that ends in  $c_\ell$ . This means  $v$  is an unknown feature node in  $T_t$  that  
 1063 distinguishes two examples in  $\Pi(v)$ , namely  $e_\ell$  and  $e_r$ . This proves Claim 2.

1064 In particular, let us consider the pool set  $\Pi(r)$  for the root  $r$  of  $T$ , we define  $\Pi(T) := \Pi(r)$ .  
 1065 In this way given  $T$ , we are able to compute the corresponding pool set.

1066 Let  $S$  be a support set for a CI  $E$ , we stay that  $B \subseteq \text{feat}(E)$  is a *branching set* for  $S$  if  
 1067 for every minimal DT  $T$  for  $E$  such that  $S \subset \text{feat}(T)$  then  $B \cap (\text{feat}(T) \setminus S) \neq \emptyset$ .

■ **Algorithm 2** Algorithm to compute the pair  $(th_L(r), th_R(r))$  for the root  $r$  of  $T$

---

**Input:** CI  $E$ , pseudo DT  $T$ ,  $S$ -feature assignment  $\alpha$  for  $T$ , feature  $f$  of the root of  $T$ , left child  $c_\ell$  of the root of  $T$ , right child  $c_r$  of the root of  $T$

**Output:** maximum threshold  $t_\ell$  in  $D_E(f)$  for  $f$  such that  $(T_{c_\ell}, \alpha)$  can be extended to a DT for  $E[f \leq t_\ell]$  and minimum threshold  $t_r$  in  $D_E(f)$  for  $f$  such that  $(T_{c_r}, \alpha)$  can be extended to a DT for  $E[f > t_r]$

```

1: function binarySearch( $E, T, \alpha, f, c_\ell, c_r$ )
2:    $D \leftarrow$  “array containing all elements in  $D_E(f)$  in
      ascending order”
3:    $L \leftarrow 0; R \leftarrow |D_E(f)| - 1; b \leftarrow 0$ 
4:   while  $L \leq R$  do
5:      $m \leftarrow \lfloor (L + R)/2 \rfloor$ 
6:     if FINDTH( $E[f \leq D[m]], T_{c_\ell}, \alpha$ ) = TRUE then
7:        $L \leftarrow m + 1; b \leftarrow 1$ 
8:     else
9:        $R \leftarrow m - 1; b \leftarrow 0$ 
10:    if  $b = 1$  then
11:       $t_\ell \leftarrow D[m]$ 
12:       $t_\ell \leftarrow D[m - 1]$  ▷ assuming that  $D[-1] = D[0] - 1$ 
13:       $L \leftarrow 0; R \leftarrow |D_E(f)| - 1; b \leftarrow 0$ 
14:      while  $L \leq R$  do
15:         $m \leftarrow \lfloor (L + R)/2 \rfloor$ 
16:        if FINDTH( $E[f > D[m]], T_{c_r}, \alpha$ ) = TRUE then
17:           $R \leftarrow m - 1; b \leftarrow 1$ 
18:        else
19:           $L \leftarrow m + 1; b \leftarrow 0$ 
20:      if  $b = 1$  then
21:         $t_r \leftarrow D[m]$ 
22:         $t_r \leftarrow D[m + 1]$  ▷ assuming that  $D[|D_E(f)|] = D[|D_E(f)| - 1] + 1$ 
23:      return  $(t_r, t_r)$ 
```

1068 ► **Lemma 22.** *There is a  $\mathcal{O}(2^{d^2/2} s^{2s+1} n^{1+o(1)} \log n)$  time algorithm that given a support set*  
 1069  *$S$  computes a branching set  $R_0$  for  $S$  of size at most  $s^{2s+3} \delta_{\max}$ .*

1070 **Proof.** Let  $E$  be a CI, a support set  $S$  for  $E$  and an integer  $s$ . We start by enumerating all  
 1071 partial DTs of size at most  $s$  such that the set of supported features is exactly  $S$ . For every  
 1072 such partial DT  $T$ , thanks to Lemma 21, we are able to obtain the set  $E_v$  for every node  
 1073  $v \in V(T)$  in time  $\mathcal{O}(2^{d^2/2} n^{1+o(1)} \log n)$ . In a leaves-to-root fashion, we are able to compute  
 1074 the set  $\Pi(v)$  for every node  $v \in V(T)$  and ultimately  $\Pi(T)$ .

1075 Let  $R(T)$  be the set of all the features in  $feat(E) \setminus S$  that distinguish at least two  
 1076 examples in  $\Pi(T)$ . The algorithm returns the set of features  $R_0$  obtained by considering the  
 1077 union of the sets  $R(T)$  over all these partial DTs  $T$  for  $S$  of size at most  $s$ . By Lemma 1 this  
 1078 algorithm runs in time  $\mathcal{O}(2^{d^2/2} s^{2s+1} n^{1+o(1)} \log n)$ .

1079 Now we show the size of  $R_0$  is bounded. By construction  $|\Pi(T)| \leq |T| \leq s$ ; for every two  
 1080 distinct elements of  $\Pi(T)$ , by definition, there are at most  $\delta_{\max}$  features that distinguish  
 1081 such two examples. This means that  $|R(T)| \leq s^2 \delta_{\max}$  and so  $R_0$  has size at most  $s^{2s+3} \delta_{\max}$ .

1082 We are left to show that  $R_0$  is a branching set for  $S$ . Let  $T$  be a minimal DT for  $E$  such  
 1083 that  $S \subset feat(T)$  and suppose by contradiction that  $R_0 \cap (feat(T) \setminus S) = \emptyset$ . In particular we  
 1084 have that  $R(T) \cap (feat(T) \setminus S) = \emptyset$ . This means that every unknown feature of  $T$  does not  
 1085 distinguish any two elements in  $\Pi(T)$ . By Claim 2,  $\Pi(T) = \Pi(r)$ , where  $r$  is the root of  $T$ , is  
 1086 a pool set and so  $T$  can not be extended to a DT for  $E$ , which is a contradiction. ◀

■ **Algorithm 3** Algorithm to compute the threshold assignment for a pseudo DT and a feature assignment.

**Input:** CI  $E$ , pseudo DT  $T$ ,  $S$ -feature assignment  $\alpha$  for  $T$

**Output:** TRUE if all examples in  $E$  can be correctly classified by  $(T, \alpha)$ , FALSE otherwise

---

```

1: function findTH( $E, T, \alpha$ )
2:    $r \leftarrow$  “root of  $T$ ”
3:   if  $r$  is a leaf then
4:     if  $E$  is not uniform then
5:       return FALSE
6:     return TRUE
7:    $c_\ell, c_r \leftarrow$  “left child and right child of  $r$ ”
8:   if  $r$  has an unknown feature then
9:      $\lambda_\ell \leftarrow$  FINDTH( $E, T_{c_\ell}, \alpha$ )
10:     $\lambda_r \leftarrow$  FINDTH( $E, T_{c_r}, \alpha$ )
11:    if  $\lambda_\ell = \text{TRUE}$  and  $\lambda_r = \text{TRUE}$  then
12:      return TRUE
13:    return FALSE
14:    $f \leftarrow \alpha(r)$ 
15:    $t \leftarrow$  BINARYSEARCH( $E, T, \alpha, c_\ell, f$ )
16:    $\lambda_r \leftarrow$  FINDTH( $E[f > t], T_{c_r}, \alpha$ )
17:   if  $\lambda_r = \text{FALSE}$  then
18:     return FALSE
19:   return TRUE

```

---

1087 ► **Lemma 23** ([23]). *Let  $E$  be a CI and let  $k$  be an integer. Then there is an algorithm that*  
1088 *in time  $\mathcal{O}(\delta_{\max}(E)^k |E|)$  enumerates all (of the at most  $\delta_{\max}(E)^k$ ) minimal support sets of*  
1089 *size at most  $k$  for  $E$ .*

1090 ► **Lemma 24** ([23]). *Let  $T$  be a DT of minimum size for  $E$  and let  $S$  be a support set*  
1091 *contained in  $\text{feat}(T)$ . Then, the set  $R = \text{feat}(T) \setminus S$  is useful.*

1092 ► **Theorem 25.** MINIMUM DECISION TREE SIZE *is fixed-parameter tractable parametrized*  
1093 *by  $\delta_{\max} + s$ .*

1094 **Proof.** We start by presenting the algorithm for MINIMUM DECISION TREE SIZE, which is  
1095 illustrated in Algorithm 4 and Algorithm 5.

1096 Given a CI  $E$  and an integer  $s$ , the algorithm returns a DT of minimum size among all  
1097 DTs of size at most  $s$  if such a DT exists and otherwise the algorithm returns **nil**. The  
1098 algorithm **minDT** starts by computing the set  $\mathcal{S}$  of all minimal support sets for  $E$  of size  
1099 at most  $s$ , which because of Lemma 23 results in a set  $\mathcal{S}$  of size at most  $(\delta_{\max}(E))^s$ . In Line 4  
1100 the algorithm then iterates over all sets  $S$  in  $\mathcal{S}$  and calls the function **minDTS** given in  
1101 Algorithm 5 for  $E, s$ , and  $S$ , which returns a DT of minimum size among all DTs  $T$  for  $E$   
1102 of size at most  $s$  such that  $S \subseteq \text{feat}(T)$ . It then updates the currently best decision tree  $B$   
1103 if necessary with the DT found by the function **minDTS**. Moreover, if the best DT found  
1104 after going through all sets in  $\mathcal{S}$  has size at most  $s$ , it is returned (in Line 9), otherwise  
1105 the algorithm returns **nil**. Finally, the function **minDTS** given in Algorithm 5 does the  
1106 following. It first computes a DT  $T$  of minimum size that uses exactly the features in  $S$   
1107 using Lemma 22. It then tries to improve upon  $T$  with the help of useful sets. That is, it  
1108 uses Lemma 22 to compute the branching set  $R_0$ . It then iterates over all (of the at most  
1109  $(\delta_{\max}(E))^s$ ) features  $f \in R_0$  (using the for-loop in Line 4), and calls itself recursively on the feature  
1110 set  $S \cup \{f\}$ . If this call finds a smaller DT, then the current best DT  $B$  is updated. Finally,  
1111 after the for-loop the algorithm either returns  $B$  if its size is less than  $s$  or **nil** otherwise.

1112 Towards showing the correctness of Algorithm 4, consider the case that  $E$  has a DT  
 1113 of size at most  $s$  and let  $T$  be a such a DT of minimum size. Because of Observation ??,  
 1114  $\text{feat}(T)$  is a support set for  $E$  and therefore  $\text{feat}(T)$  contains a minimal support set  $S$  of size  
 1115 at most  $s$ . Because the for-loop in Line 4 of Algorithm 4 iterates over all minimal support  
 1116 sets of size at most  $s$  for  $E$ , it follows that Algorithm 5 is called with parameters  $E$ ,  $s$ , and  
 1117  $S$ . If  $\text{feat}(T) = S$ , then  $B$  is set to a DT for  $E$  of size  $|T|$  in Line 2 of Algorithm 5 and the  
 1118 algorithm will output a DT of size at most  $|T|$  for  $E$ . If, on the other hand,  $\text{feat}(T) \setminus S \neq \emptyset$ ,  
 1119 then because  $T$  has minimum size and  $S$  is a support set for  $E$  with  $S \subseteq \text{feat}(T)$ , we obtain  
 1120 from Lemma 24 that the set  $R = \text{feat}(T) \setminus S$  is useful for  $S$ . Therefore, because of Lemma 22,  
 1121  $R$  has to contain a feature  $f$  from the set  $R_0$  computed in Line 3. It follows that Algorithm 5  
 1122 is called with parameters  $E$ ,  $s$ , and  $S \cup \{v\}$ . From now onwards the argument repeats and  
 1123 since  $R_0 \neq \emptyset$  the process stops after at most  $s - |S|$  recursive calls after which a DT for  $E$  of  
 1124 size at most  $|T|$  will be computed in Line 2 of Algorithm 5. Finally, it is easy to see that if  
 1125 Algorithm 4 outputs a DT  $T$ , then it is a valid solution. This is because,  $T$  must have been  
 1126 computed in Line 2 of Algorithm 5, which implies that  $T$  is a DT for  $E$ . Moreover,  $T$  has  
 1127 size at most  $s$ , because of Line 8 in Algorithm 4.

1128 To analyse the run-time of the algorithm, we first remark that the whole algorithm can  
 1129 be seen as a bounded-depth search tree algorithm, i.e., a branching algorithm with small  
 1130 recursion depth and few branches at every node. In particular, every recursive call adds at  
 1131 least one feature to the set of features bounding the recursion depth to at most  $s$ . Moreover,  
 1132 every feature that is added is either added in Line 2 of Algorithm 4, when enumerating  
 1133 all minimal support sets, in which case there are at most  $\delta_{\max}(E)$  branches or the feature  
 1134 is added in Line 5 of Algorithm 5, in which case there are at most  $|R_0| \leq s^{2s+3} \delta_{\max}(E)$   
 1135 branches. It follows that the algorithm can be seen as a branching algorithm of depth  
 1136 at most  $s$  with at most  $s^{2s+3} \delta_{\max}(E) = \max\{s^{2s+3} \delta_{\max}(E), \delta_{\max}(E)\}$  branches at every  
 1137 step. Therefore, the total run-time of the algorithm is at most the number of nodes in  
 1138 the branching tree, i.e., at most  $(s^{2s+3} \delta_{\max}(E))^s$ , times the maximum time required in  
 1139 one recursive call. Now the maximum time required for one recursive call is dominated  
 1140 by the time spend in Line 2 of Algorithm 5, i.e., the time required to compute a DT of  
 1141 minimum size using exactly the features in  $S$  with the help of Theorem ??, which is at  
 1142 most  $2^{\mathcal{O}(s^2)} \|E\|^{1+o(1)} \log \|E\|$ . Therefore, we obtain  $(s^{2s+3} \delta_{\max}(E))^s 2^{\mathcal{O}(s^2)} \|E\|^{1+o(1)} \log \|E\|$   
 1143 as the total run-time of the algorithm, which shows that DTS is fixed-parameter tractable  
 1144 parameterized by  $s + \delta_{\max}(E)$ . ◀

■ **Algorithm 4** Main method for finding a DT of minimum size.

**Input:** CI  $E$  and integer  $s$

**Output:** DT for  $E$  of minimum size (among all DTs of size at most  $s$ ) if such a DT exists, otherwise  
 nil

```

1: function minDT( $E, s$ )
2:    $S \leftarrow$  "set of all minimal support sets for  $E$  of size at most  $s$  using Lemma 23"
3:    $B \leftarrow$  nil
4:   for  $S \in S$  do
5:      $T \leftarrow$  minDTS( $E, s, S$ )
6:     if ( $T \neq$  nil) and ( $B =$  nil or  $|B| > |T|$ ) then
7:        $B \leftarrow T$ 
8:   if  $B \neq$  nil and  $|B| \leq s$  then
9:     return  $B$ 
10:  return nil
  
```

■ **Algorithm 5** Method for finding a DT of minimum size using at least the features in a given support set  $S$ .

**Input:** CI  $E$ , integer  $s$ , support set  $S$  for  $E$  with  $|S| \leq s$

**Output:** DT of minimum size among all DTs  $T$  for  $E$  of size at most  $s$  such that  $S \subseteq \text{feat}(T)$ ; if no such DT exists, **nil**

---

```

1: function minDTS( $E, s, S$ )
2:    $B \leftarrow$  “compute a DT of minimum size for  $E$  using exactly the features in  $S$  using Theorem ??”
3:    $R_0 \leftarrow$  “compute the branching set  $R_0$  for  $S$  using Lemma 22”
4:   for  $f \in R_0$  do
5:      $T \leftarrow \text{minDTS}(E, s, S \cup \{f\})$ 
6:     if  $T \neq \text{nil}$  and  $|T| < |B|$  then
7:        $B \leftarrow T$ 
8:   if  $|B| \leq s$  then
9:     return  $B$ 
10:  return nil

```

---

## 1145 5 Conclusion

1146 We have initiated the study of the parameterized complexity of learning DTs from data. Our  
 1147 main tractability result provides novel insights into the structure of DTs and is based on  
 1148 the NLC-width parameter that seems to be well suited to measure the complexity of input  
 1149 instances for the problem.

1150 The problem of learning DTs comes in many variants and flavors, which opens up a wide  
 1151 range of new research directions to explore. For instance:

- 1152 ■ What other (structural) parameters can be exploited to efficiently learn DTs? Is learning  
 1153 DTs of small size fixed-parameter tractable parameterized by the rank-width of  $G_I(E)$ ?
- 1154 ■ Instead of learning DTs of small size, one often wants to learn DTs of small height.  
 1155 Therefore, it is natural to ask whether our approach can be also used in this setting.  
 1156 While one can adapt our approach to obtain an XP-algorithm for learning DTs of small  
 1157 height parameterized by NLC-width, it is not clear to us whether the problem also allows  
 1158 for an fpt-algorithm.
- 1159 ■ Can we extend our approach to CIs, where features range over an arbitrary domain? In  
 1160 this case, one usually still uses DTs that make binary decisions (i.e. whether a feature is  
 1161 smaller equal or larger than a given threshold). While it is relatively easy to see that our  
 1162 approach can be extended if the domain’s size (for every feature) is bounded or used as  
 1163 an additional parameter, it is not clear what happens if the size of the domain is allowed  
 1164 to grow arbitrarily.
