<sup>7</sup> We consider the NP-hard problem of finding a smallest decision tree which represents a given partially  
<sup>8</sup> defined Boolean formula. We establish fixed-parameter tractability of the problem with respect to  
<sup>9</sup> the NLC-width of the instance. We formulate a dynamic programming procedure which utilizes  
<sup>10</sup> the NLC-decomposition of the instance. For this to work, we establish a succinct representation  
<sup>11</sup> of partial solutions, so that the space and time requirements of each dynamic programming step  
<sup>12</sup> remain bounded in terms of the NLC-width.

17    **1    Introduction**

18    Decision trees have proved to be extremely useful tools for the describing, classifying,  
 19    generalizing data [18, 22, 25]. In this paper, we consider decision trees for *classification*  
 20    *instances (CIs)*, consisting of a finite set  $E$  of *examples* (also called *feature vectors*) over a  
 21    finite set  $F$  of *features*. Each example  $e \in E$  is a function  $e : F \rightarrow \{0, 1\}$  which determines  
 22    whether the feature  $f$  is true or false for  $e$ . Moreover,  $E$  is given as a partition  $E^+ \uplus E^-$  into  
 23    positive and negative examples. For instance, examples could represent medical patients and  
 24    features diagnostic tests; a patient is positive or negative corresponding to whether they have  
 25    been diagnosed with a certain disease or not. CIs are also called *partially* or *incompletely*  
 26    *defined Boolean functions*, as we can consider the features as Boolean variables, and examples  
 27    as truth assignments that evaluate to 0 (for positive examples) or 1 (for negative examples).  
 28    CIs have been studied as a key concept for the logical analysis of data and in switching  
 29    theory [4, 6, 5, 7, 8, 17, 20].

30    Because of their simplicity, decision trees are particularly attractive for providing in-  
 31    terpretable models of the underlying CI, an aspect whose importance has been strongly  
 32    emphasized over the recent years [10, 12, 15, 19, 21]. In this context, one prefers *small trees*,  
 33    as they are easier to interpret and require fewer tests to make a classification. Small trees  
 34    are also preferred in view of the parsimony principle (Occam's Razor) since small trees are  
 35    expected to generalize better to new data [2]. However, finding a small decision tree, as  
 36    formulated in the following decision problem, is NP-complete [16].

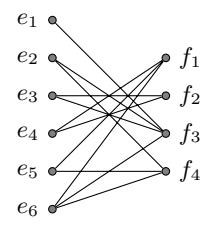

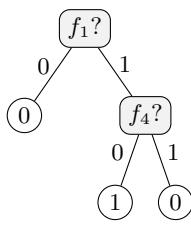

37    MINIMUM DECISION TREE SIZE (DTS): given a CI  $E = E^+ \uplus E^-$  and an integer  $s$ ,  
 38    is there a decision tree with at most  $s$  nodes for  $E$ ?

39    Given this complexity barrier, we propose a fixed-parameter algorithm for the problem,  
 40    which exploits the input CI's hidden structure. The *incidence graph* of a CI is the bipartite  
 41    graph  $G_I(E)$  whose vertices are the examples on one side and the features on the other,  
 42    where an example  $e$  is adjacent with a feature  $f$  if and only if  $e(f) = 1$ . Figure 1 shows a CI  
 43    and a smallest decision tree for it, as well as the incidence graph.

44    Key to our algorithm are new notions for succinctly representing decision trees that  
 45    correspond to subtrees of the incidence graph's tree decomposition. Based on that, we can  
 46    carry out a dynamic programming (DP) procedure along the tree decomposition.

47    While the DP approach using treewidth is quite well understood and can often be quite  
 48    easily designed for problems on graphs (or more generally problems whose solutions can be  
 49    represented in terms of the graph for which the tree decomposition is given), the same DP  
 50    approach can become rather involved if applied to problems whose solutions have no or only  
 51    minor resemblance to the graph for which one is given a tree decomposition. Probably the  
 52    most prominent example for this is the celebrated result by Bodlaender [3], where he uses a

$E$	$f_1$	$f_2$	$f_3$	$f_4$
$e_1 \in E^-$	0	0	1	0
$e_2 \in E^-$	0	0	1	1
$e_3 \in E^-$	0	1	1	0
$e_4 \in E^-$	1	1	0	0
$e_5 \in E^+$	1	0	0	1
$e_6 \in E^+$	1	0	1	1

■ **Figure 1** A CI  $E = E^+ \uplus E^-$  with six examples and four features (left), a decision tree with 5 nodes that classifies  $E$  (middle), the incidence graph  $G_I(E)$  (right).

53 DP approach on an approximate tree decomposition to compute the exact treewidth of a  
 54 graph; here, the solutions are tree decompositions, which are complex structures that cannot  
 55 easily be represented in terms of the graph. Other prominent examples include a DP approach  
 56 to compute the exact treedepth [26] or clique-width [14] using an optimal tree decomposition.  
 57 We face a similar problem, since solutions in our case are decision trees that do not bear  
 58 any resemblance to the incidence graph for which we are given the tree decomposition. The  
 59 main obstacle to overcome, therefore, is the design of the DP-records for our DP algorithm.  
 60 That is, a record for a node  $b$  in a tree decomposition for the incidence graph of  $E$  needs  
 61 to provide a compact representation of partial solutions, i.e. partial solutions in the sense  
 62 that they represent the part of the solution for the whole instance  $E$  that corresponds to the  
 63 sub-instance induced by all features and examples contained in the bags in the subtree of  
 64 the tree decomposition rooted at the current node  $b$ . We overcome this obstacle in Section 3,  
 65 where we also provide intuitive descriptions and motivation for the definition of the records  
 66 (Subsection 3.1).

## 67 2 Preliminaries

### 68 2.1 Parameterized Complexity

69 We give some basic definitions of Parameterized Complexity and refer for a more in-depth  
 70 treatment to other sources [9, 13]. Parameterized complexity considers problems in a two-  
 71 dimensional setting, where a problem instance is a pair  $(I, k)$ , where  $I$  is the main part  
 72 and  $k$  is the parameter. A parameterized problem is *fixed-parameter tractable* if there exists  
 73 a computable function  $f$  such that instances  $(I, k)$  can be solved in time  $f(k)\|I\|^{O(1)}$ .

### 74 2.2 Graphs and NLC-width

75 We will assume that the reader is familiar with basic graph theory (see, e.g. [11, 1]). We  
 76 consider (vertex and edge labelled) undirected graphs. Let  $G = (V, E)$  be an undirected  
 77 graph. We write  $V(G) = V$  and  $E(G) = E$  for the sets of vertices and edges of  $G$ , respectively.  
 78 We denote an edge between  $u \in V$  and  $v \in V$  as  $\{u, v\}$ . For a set  $V' \subseteq V$  of vertices we let  
 79  $G[V']$  denote the graph induced by the vertices in  $V'$ , i.e.  $G[V']$  has vertex set  $V'$  and edge  
 80 set  $E \cap \{\{u, v\} \mid u, v \in V'\}$  and we let  $G - V'$  denote the graph  $G[V \setminus V']$ . For a set  $E' \subseteq E$   
 81 of edges we let denote  $G - E'$  the graph with vertex set  $V$  and edge set  $E \setminus E'$ .

82 A *k-graph* is a pair  $(G, \lambda)$ , where  $G = (V, E)$  is an undirected graph and  $\lambda : V \rightarrow [k]$  is a  
 83 *vertex label mapping* that labels every vertex  $v \in V$  with a label  $\lambda(v)$  from  $[k]$ . We call the  
 84 *k-graph* consisting of exactly one vertex  $v$  (say, labeled by  $i$ ) an *initial k-graph* and denote it  
 85 by  $i(v)$ .

86 Node label control-width (*NLC-width*) is a graph parameter, defined as follows [28]: Let  
 87  $k \in \mathbb{N}$  be a positive integer. An *k-NLC-expression tree* of a graph  $G = (V, E)$  is a subcubic  
 88 tree  $B$ , where every node  $b$  of  $B$  is associated with a *k-graph* (denoted by  $(G_b, \lambda_b)$ ), such  
 89 that:

- 90 1. Every leaf represents an initial *k-graph*  $i(v)$  with  $i \in [k]$  and  $v \in V$ .
- 91 2. Every non-leaf node  $b$  with one child  $c$  is a *relabeling node* and is associated with a  
 92 relabelling function  $R_b : [k] \rightarrow [k]$ . Moreover,  $G_b$  is obtained from  $G_c$  after relabelling all  
 93 vertices of  $G_c$  with label  $i$  to label  $R_b(i)$  for every  $i \in [k]$ .
- 94 3. Every non-leaf node  $b$  with two children, i.e., a left child  $l$  and a right child  $r$ , is a *join*  
 95 *node* and is associated with a *join matrix*, i.e., a binary  $k \times k$  matrix  $M_b$ . Moreover,

96         $(G_b, \lambda_b)$  is obtained from the disjoint union of  $(G_l, \lambda_l)$  and  $(G_r, \lambda_r)$  after adding an edge  
 97        from all vertices labeled  $i$  in  $G_l$  to all vertices labeled  $j$  in  $G_r$  whenever  $M_b[i, j] = 1$ .

98        4.  $G$  is equal to the  $G_r$  for the root node  $r$  of  $B$ .

99        The NLC-width of a graph  $G$ , denoted by  $nlcw(G)$ , is the minimum  $k$  for which  $G$  has  
 100      a  $k$ -NLC-expression tree. A  $k$ -NLC-expression tree is *nice* if every relabelling node has a  
   101      relabelling function  $R : [k] \rightarrow [k]$  such that for some  $i, j \in [k]$ ,  $R(i) = j$  and  $R(\ell) = \ell$  for all  
   102       $\ell \in [k] \setminus \{i\}$ . Clearly, given a  $k$ -NLC-expression tree, a nice  $k$ -NLC-expression tree can be  
   103      found in polynomial time; simply replace every relabelling node (that relabels more than one  
   104      label at a time) by a sequence of relabelling nodes.

105       Let  $b$  be a node in a  $k$ -NLC-expression tree of a graph  $G$ . We denote by  $V_b$  the set of  
 106      vertices of  $G_b$ . By the definition of a  $k$ -NLC-expression tree, if  $u, v \in V_b$  have the same label  
   107      in  $(G_b, \lambda_b)$  and  $w \in V(G) \setminus V_b$ , then  $u$  is adjacent to  $w$  in  $G$  if and only if  $v$  is.

108       Computing the NLC-width of a graph is NP-hard [?]. However, it is sufficient to use the  
 109      algorithm of Seymour and Oum [?], which returns a  $c$ -expression for some  $c \leq 2^{3cw(G)+2} - 1$   
   110      in  $O(n^9 \log n)$  time, or the later improvements of Oum [24] and Hliněný and Oum [?]  
   111      that provide cubic-time algorithms which yield a  $c$ -expression for some  $c \leq 8^{cw(G)} - 1$  and  
   112       $c \leq 2^{cw(G)+1} - 1$ , respectively.

113       should it be  $nlcw$ , or should we define  $cw$  and say it's approximation?

## 114      2.3 Classification Problems

115       An *example*  $e$  is a function  $e : \text{feat}(e) \rightarrow \{0, 1\}$  defined on a finite set  $\text{feat}(e)$  of *features*. For  
 116      a set  $E$  of examples, we put  $\text{feat}(E) = \bigcup_{e \in E} \text{feat}(e)$ . We say that two examples  $e_1, e_2$  *agree*  
   117      on a feature  $f$  if  $f \in \text{feat}(e_1)$ ,  $f \in \text{feat}(e_2)$  and  $e_1(f) = e_2(f)$ . If  $f \in \text{feat}(e_1)$ ,  $f \in \text{feat}(e_2)$   
   118      but  $e_1(f) \neq e_2(f)$ , we say that the examples *disagree on*  $f$ .

119       A *classification instance* (CI) (also called a *partially defined Boolean function* [17])  
 120       $E = E^+ \uplus E^-$  is the disjoint union of two sets of examples, where for all  $e_1, e_2 \in E$  we have  
   121       $\text{feat}(e_1) = \text{feat}(e_2)$ . The examples in  $E^+$  are said to be *positive*; the examples in  $E^-$  are  
   122      said to be *negative*. A set  $X$  of examples is *uniform* if  $X \subseteq E^+$  or  $X \subseteq E^-$ ; otherwise  $X$  is  
   123      *non-uniform*.

124       Given a CI  $E$ , a subset  $F \subseteq \text{feat}(E)$  is a *support set* of  $E$  if any two examples  $e_1 \in E^+$   
 125      and  $e_2 \in E^-$  disagree in at least one feature of  $F$ . Finding a smallest support set, denoted  
   126      by  $\text{MSS}(E)$ , for a classification instance  $E$  is an NP-hard task [17, Theorem 12.2].

127       We define the *incidence graph* of  $E$ , denoted by  $G_I(E)$ , as the bipartite graph with  
 128      partition  $(E, \text{feat}(E))$  having an edge between an example  $e \in E$  and a feature  $f \in \text{feat}(e)$  if  
   129       $f(e) = 1$ .

## 130      2.4 Decision Trees

131       A *decision tree* (DT) (or *classification tree*) is a rooted tree  $T$  with vertex set  $V(T)$  and arc  
 132      set  $A(T)$ , where each non-leaf node (called a *test*)  $v \in V(T)$  is labelled with a feature  $\text{feat}(v)$ ,  
   133      each non-leaf node  $v$  has exactly two out-going arcs, a *left arc* and a *right arc*, and each leaf  
   134      is either a *positive* or a *negative* leaf. We write  $\text{feat}(T) = \{v \in V(T) \mid \text{feat}(v)\}$ .

135       Consider a CI  $E$  and a decision tree  $T$  with  $\text{feat}(T) \subseteq \text{feat}(E)$ . For each node  $v$  of  $T$  we  
 136      define  $E_T(v)$  as the set of all examples  $e \in E$  such that for each left (right, respectively)  
   137      arc  $(u, v)$  on the unique path from the root of  $T$  to  $v$  we have  $e(\text{feat}(v)) = 0$  ( $e(\text{feat}(v)) = 1$ ,  
   138      respectively).  $T$  *correctly classifies* an example  $e \in E$  if  $e$  is a positive (negative) example  
   139      and  $e \in E_T(v)$  for a positive (negative) leaf. We say that  $T$  *classifies*  $E$  (or simply that  $T$  is

<sup>140</sup> a DT for  $E$ ) if  $T$  correctly classifies every example  $e \in E$ . See Figure 1 for an illustration of  
<sup>141</sup> a CI, its incidence graph, and a DT that classifies  $E$ .

<sup>142</sup> The size of  $T$  is its number of nodes, i.e.  $|V(T)|$ . We consider the following problem.

MINIMUM DECISION TREE SIZE (DTS)

<sup>143</sup> Input: A classification instance  $E$  and an integer  $s$ .  
<sup>144</sup> Question: Is there a decision tree of size at most  $s$  for  $E$ ?

<sup>145</sup> We now give some simple auxiliary lemmas that are required by our algorithm.

<sup>146</sup> ▶ **Lemma 1.** *Let  $A$  be a set of features of size  $a$ . Then the number of DTs of size at most  $s$  that use only features in  $A$  is at most  $a^{2s+1}$  and those can be enumerated in  $\mathcal{O}(a^{2s+1})$  time.*

<sup>147</sup> **Proof.** We start by counting the number of trees  $T$  with  $n$  nodes that can potentially underlie  
<sup>148</sup> a DT with  $n$  nodes. Note that there is one-to-one correspondence between trees  $T$  that  
<sup>149</sup> underlie a DT with  $n$  nodes and unlabelled rooted ordered binary trees with  $n$  nodes (where  
<sup>150</sup> ordered refers to an ordering of the at most 2 child nodes). Since it is known that the number  
<sup>151</sup> of unlabelled rooted ordered binary trees with  $n$  nodes is equal to the  $n$ -th Catalan number  
<sup>152</sup>  $C_n$  and that those trees can be enumerated in  $\mathcal{O}(C_n)$  time [27], we already obtain that we  
<sup>153</sup> can enumerate all of the at most  $C_n$  possible trees  $T$  underlying a DT of size  $n$  in  $\mathcal{O}(C_n)$   
<sup>154</sup> time. Therefore, there are at most  $sC_s$  possible trees of size at most  $s$  that can underlie a  
<sup>155</sup> DT with at most  $s$  nodes and those can be enumerated in  $\mathcal{O}(sC_s)$  time. It now remains  
<sup>156</sup> to bound the number of possible feature assignments  $feat(f)$  for these trees as well as the  
<sup>157</sup> number of possibilities for the leave nodes that can be either labelled positive or negative.  
<sup>158</sup> Since we can assume that  $a \geq 2$ , we obtain that the number of possible feature assignments  
<sup>159</sup> (and labellings of leaf-nodes) of a tree  $T$  with  $n$  nodes is at most  $a^n$ . Taking everything  
<sup>160</sup> together, we obtain that there are at most  $sC_s a^s \leq s4^s a^s \leq a^{2s+1}$  many DTs of size at most  
<sup>161</sup>  $s$  using only features in  $A$  and those can be enumerated in  $\mathcal{O}(a^{2s+1})$  time. ◀

<sup>162</sup> ▶ **Lemma 2.** *Let  $A$  be a set of features of size  $a$ . There are at most  $a^{2^{a+1}+3}$  inclusion-wise  
<sup>163</sup> minimal DTs using only features in  $A$  and these can be enumerated in  $\mathcal{O}(a^{2^{a+1}+3})$  time.*

<sup>164</sup> **Proof.** Note that an inclusion-wise minimal DT  $T$  that uses only features in  $A$  has at most  
<sup>165</sup>  $2^a + 1$  nodes; this is because every feature appears at most once on every path  $T$ . Therefore, we  
<sup>166</sup> obtain from Lemma 1 that the number of choices for  $T$  is at most  $a^{2(2^a+1)+1} = a^{2^{a+1}+3}$ . ◀

<sup>167</sup> ▶ **Lemma 3.** *Let  $E$  be a CI. Then one can decide whether  $E$  has a DT and if so output a  
<sup>168</sup> DT of minimum size for  $E$  in time  $\mathcal{O}((2^{|E|})^{4|E|-1})$ .*

<sup>169</sup> **Proof.** Note first that  $|feat(E)| \leq 2^{|E|}$  since we can assume that  $E$  does not contain two  
<sup>170</sup> equivalent features. Moreover,  $E$  has a DT if and only if  $feat(E)$  is a support set, which can be  
<sup>171</sup> checked in time  $\mathcal{O}(|E|^2 |feat(E)|)$  by checking, for every pair of positive and negative examples  
<sup>172</sup> in  $E$ , whether there is a feature that distinguishes them. If this is not the case, we output **NO**,  
<sup>173</sup> so assume that  $E$  has a DT. Note that any inclusion-wise minimal DT for  $E$  has at most  $|E|$   
<sup>174</sup> leaves and therefore size at most  $2|E| - 1$ . We can therefore employ Lemma 1 to enumerate  
<sup>175</sup> all inclusion-wise minimal potential DTs for  $E$  in time  $\mathcal{O}((2^{|E|})^{2(2|E|-1)+1}) \in \mathcal{O}((2^{|E|})^{4|E|-1})$ .  
<sup>176</sup> For every such tree we then check whether it is indeed a DT for  $E$  and return a DT for  $E$  of  
<sup>177</sup> minimum size found during this process. ◀

178 **3 An FPT-Algorithm for NLC-width**

179 In this section, we present our main result, i.e. we will show that DTS is fixed-parameter  
 180 tractable parameterized by NLC-width.

181 ▶ **Theorem 4.** *Let  $E$  be a CI, let  $B$  be an NLC-decomposition of width  $\omega$  for  $G_I(E)$ , and  
 182 let  $s$  be an integer. Then, deciding whether  $E$  has a DT of size at most  $s$  is fixed-parameter  
 183 tractable parameterized by  $\omega$ .*

184 ▶ **Corollary 5.** *DTS is fixed-parameter tractable parameterized by NLC-width.*

todo: Due to  
proposition ...

185 In principle, we will use a dynamic programming algorithm along the NLC-decomposition  
 186 ( $B, \chi$ ) of  $G_I(E)$  that computes a set of records for every node  $b$  of  $B$  in a bottom-up manner.  
 187 Each record will represent an equivalence class of solutions (DTs) for the whole instance  
 188 restricted to the examples and features contained in the current subtree rooted in  $b$ , i.e.  
 189 the examples and features contained in  $\chi(b)$ . Before we continue with the formal notions  
 190 and definitions required to define the records, we want to illustrate the main ideas and  
 191 motivations. In what follows let  $B$  be an NLC-decomposition of  $G_I(E)$  of width  $k$ . For  
 192  $b \in V(B)$ , we write  $\text{feat}(b)$  and  $\text{exam}(b)$  for the sets  $\chi(b) \cap \text{feat}(E)$  and  $\chi(b) \cap E$ , respectively.

193 **3.1 Description of the Main Ideas Behind the Algorithm**

194 Consider a node  $b$  of  $B$ . To simplify the presentation, we will sometime refer to the features  
 195 and examples in  $\chi(B_b) \setminus \chi(b)$  as *forgotten* features and examples and we refer to the features  
 196 and examples in  $(\text{feat}(E) \cup E) \setminus \chi(B_b)$  as *future* features and examples. We start with some  
 197 simple observations that follow immediately from the properties of tree decompositions.

198 ▶ **Observation 6.(1)**  *$e(f) = 0$  for every forgotten example  $e \in \text{exam}(B_b) \setminus \text{exam}(b)$  and  
 199 future feature  $f \in \text{feat}(E) \setminus \text{feat}(B_b)$ ,*  
 200 (2)  *$e(f) = 0$  for every future example  $e \in E \setminus \text{exam}(B_b)$  and forgotten feature  $f \in \text{feat}(B_b) \setminus  
 201 \text{feat}(b)$ ;*

202 **Proof.** Towards showing (1), let  $e$  be an example in  $\text{exam}(B_b) \setminus \text{exam}(b)$  and let  $f$  be a  
 203 feature in  $\text{feat}(E) \setminus \text{feat}(B_b)$ . We claim that because  $(T, \chi)$  is a tree decomposition of  $G_I(E)$ ,  
 204 the graph  $G_I(E)$  cannot contain an edge between  $e$  and  $f$ , which implies that  $e(f) = 0$ .  
 205 Suppose for a contradiction that this is not the case, i.e.  $\{e, f\} \in E(G_I(E))$ . Then, because  
 206 of property (T1) of a tree decomposition, there must exist a node  $b'$  such that  $e, f \in \chi(b')$ .  
 207 But then, if  $b' \in V(B_b)$  we obtain that  $f \notin \chi(b')$ . Similarly, if  $b' \in V(B \setminus B_b)$ , we obtain  
 208 that  $e \notin \chi(b')$  since otherwise  $e$  would violate property (T2) of a tree decomposition. This  
 209 completes the proof for (1); the proof for (2) is analogous. ◀

210 Informally, Observation 6 shows that forgotten examples cannot be distinguished by  
 211 future features and future examples cannot be distinguished by forgotten features. Consider  
 212 a DT  $T$  for  $E$  and a node  $b$  of  $B$ . For a set  $W$  containing features and examples from  $E$ , we  
 213 denote by  $E[W]$  the sub-instance of  $E$  induced by the features and examples in  $W$ . Our aim  
 214 is to obtain a compact representation (represented by records) of the partial solution for the  
 215 sub-instance  $E[\chi(B_b)]$  of  $E$  induced by the features and examples in  $\chi(B_b)$  represented by  $T$ .

216 Intuitively, such a compact representation has to (1) represent a partial solution (DT)  
 217 for the examples in  $\text{exam}(B_b)$  and (2) retain sufficient information about the structure of  $T$   
 218 in order to decide whether it can be extended to a DT that also classifies the examples in  
 219  $E \setminus \text{exam}(B_b)$ .

todo: adjust to  
NLC-width

220 For illustration purposes let us first consider the simplified case that  $\text{exam}(b) = \emptyset$ . Because  
 221 of Observation 6 (1), this implies that every forgotten example goes to the left child of  
 222 any node  $t$  in  $T$  that is assigned a future feature. Therefore, under the assumption that  
 223  $\text{exam}(b) = \emptyset$  the DT  $T'$  obtained from  $T$  after:

- 224 ■ removing the subtree  $T_r$  of  $T$  for every right child  $r$  of a node  $t$  of  $T$  with  $\text{feat}(t) \in$   
 225  $\text{feat}(E) \setminus \text{feat}(B_b)$  and replacing  $t$  with an edge from its parent in  $T$  to its left child in  $T$

226 is a DT for  $E[\chi(B_b)]$ . Note that this means that under the rather strong assumption  
 227 that  $\text{exam}(b) = \emptyset$ , the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$  is itself a DT  
 228 using only features in  $\text{feat}(B_b)$ ; we will see later that unfortunately this is no longer the case  
 229 if  $\text{exam}(b) \neq \emptyset$ . Note that even though  $T'$  is a DT for  $E[B_b]$ , it does not yet constitute a  
 230 compact representation, since the number of features it uses in  $\text{feat}(B_b) \setminus \text{feat}(b)$  is potentially  
 231 unbounded. However, we obtain from Observation 6 (2) that every future example will end  
 232 up in the left child of every node  $t$  of  $T'$  that is assigned a forgotten feature. This means  
 233 that to decide whether  $T'$  can be extended to a DT for the whole instance, the nodes that  
 234 are assigned forgotten features are not important. In fact, the only nodes in  $T'$  that can be  
 235 important for the classification of future examples are the nodes that are assigned features  
 236 in  $\text{feat}(b)$ . That is, it is sufficient to remember the DT  $T''$  obtained from  $T'$  after:

- 237 ■ removing the subtree  $T_r$  of  $T'$  for every right child  $r$  of a node  $t$  of  $T'$  with  $\text{feat}(t) \in$   
 238  $\text{feat}(B_b) \setminus \text{feat}(b)$  and replacing  $t$  with an edge from its parent in  $T'$  to its left child in  $T'$ .

239 Since the number of possible DT  $T''$  is clearly bounded in terms of the number of features  
 240 in  $\text{feat}(b)$  (and therefore in terms of the treewidth of  $G_I(E)$ ), this would already give us the  
 241 compact representation that we are looking for. However, this only works in the case that  
 242  $\text{exam}(b) = \emptyset$ , which is clearly not the case in general.

243 So let us now consider the general case with  $\text{exam}(b) \neq \emptyset$ . The first difference now is  
 244 that the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$  is no longer a DT that only  
 245 uses features in  $\text{feat}(B_b)$ . In fact, it could even be the case that  $E[\chi(B_b)]$  does not have a  
 246 DT, because there could exist examples in  $\text{exam}(b)$  that can only be distinguished using  
 247 the features in  $\text{feat}(E) \setminus \text{feat}(B_b)$ . This means that we have to allow our partial solution for  
 248  $E[\chi(B_b)]$  to use future features. Fortunately, we do not need to know which exact future  
 249 feature is used by our partial solution but it suffices to know that a future feature is used and  
 250 how it behaves w.r.t. the examples in  $\text{exam}(b)$ ; this is because Observation 6 (1) implies that  
 251 a future feature is used in a partial solution only for the purpose of distinguishing examples  
 252 in  $\text{exam}(b)$ . Moreover, because every forgotten example ends up in the left child of any node  
 253  $t$  of  $T$  that uses a future feature, we only need to remember the left child for those nodes.  
 254 Also, we only need to remember occurrences of those nodes (using future features) if at least  
 255 one example in  $\text{exam}(b)$  ends up in the right child of such a node; otherwise the node has  
 256 no influence on the classification of examples in  $\text{exam}(B_b)$ . Finally, we cannot simply forget  
 257 nodes that use forgotten features (as we could in the case that  $\text{exam}(b) = \emptyset$ ). This is because  
 258 we need to know exactly where the examples in  $\text{exam}(b)$  end up at. For instance, if such  
 259 an example in  $\text{exam}(b)$  ends up in the right child of a node using a future feature, we need  
 260 to know that this is the case because this means that the example has to be classified in  
 261 this place at a later stage of the algorithm. Nevertheless, we do not need to remember all  
 262 occurrences of nodes using forgotten features, but only those for which there is at least one  
 263 example in  $\text{exam}(b)$  that ends up in the right child of the node. Similarly, we do not need  
 264 to remember the exact forgotten feature that is used but only how it behaves towards the  
 265 examples in  $\text{exam}(b)$ . In summary, we only need to remember the full information about

266 the nodes of  $T$  that use a feature in  $\text{feat}(b)$ . For all other nodes, i.e. nodes that use either  
 267 forgotten or future features, we only need to remember such a node, if at least one example  
 268 in  $\text{exam}(b)$  ends up in its right child. Moreover, even if this is the case, we only need to  
 269 remember the following for such nodes:

- 270 ■ whether it uses a future or a forgotten feature and  
 271 ■ how it behaves w.r.t. the examples in  $\text{exam}(b)$ .

272 With these ideas in mind, we are now ready to provide a formal definition of the compact  
 273 representation of the part of  $T$  that takes care of the sub-instance  $E[\chi(B_b)]$ .

### 274 3.2 Formal Definition of Records and Preliminary Results

275 In the following, let  $E$  be a CI and let  $B$  be a  $k$ -NLC-expression tree for  $G_I(E)$ . Consider a  
 276 node  $b$  of  $B$ . Recall that  $b$  is either a leaf node associated with a  $k$ -graph  $i(v)$ , a relabelling  
 277 node with 1 child and with relabelling function  $R_b$ , or a join node with a left child, a right  
 278 child and a join matrix  $M_b$ . Moreover, recall that  $(G_b, \lambda_b)$  is the  $k$ -graph associated with  $b$   
 279 (whose unlabeled version is a subgraph of  $G$ ) and  $V_b$  is the set of vertices of  $G_b$ . Additionally,  
 280 we will use the following notation. We denote by  $\text{feat}(b)$  the set  $V_b \cap \text{feat}(E)$  of features in  
 281  $V_b$  and by  $\text{exam}(b)$  the set  $V_b \cap E$  of examples in  $V_b$ .

282 Consider a node  $b$  of  $B$ . Let  $L$  be a set of labels (usually  $L = [k]$ ). For a subset  $L' \subseteq L$ ,  
 283 we denote by  $\overline{L'}$  the set  $L \setminus L'$ . For a label  $l \in L$ , we introduce a new feature  $f_l$ , which we  
 284 will call a *forgotten feature*. Moreover, for a subset  $L' \subseteq L$  of labels, we introduce a new  
 285 feature  $f_{L'}$ , which we call an *future (or introduce) feature*. Let  $F_L = \{f_l \mid l \in L\}$  be the set  
 286 of all forgotten features and let  $I_L = \{f_{L'} \mid L' \subseteq L\}$  be the set of all future features w.r.t.  
 287  $L$ . To distinguish features in  $\text{feat}(E)$  from forgotton and future features, we will sometimes  
 288 refer to them as *real features*.

289 Let  $T$  be a DT and  $t \in V(T)$ . We say that a node  $t_A$  is a *left (right) ancestor* of  $t$   
 290 if  $t$  is contained in the subtree of  $T$  rooted at the left (right) child of  $t_A$ . We denote by  
 291  $\text{anc}_T^L(t)$  ( $\text{anc}_T^R(t)$ ), or simply  $\text{anc}^L(t)$  ( $\text{anc}^R(t)$ ) if  $T$  is clear from the context, the set of all  
 292 left (right) ancestors of  $t$  in  $T$ . We denote by  $\text{anc}(t)$  the set of all *ancestors* of  $t$  in  $T$ , i.e.,  
 293  $\text{anc}(t) = \text{anc}^L(t) \cup \text{anc}^R(t)$ .

294 Let  $T$  be a DT and  $t \in V(T)$  be an inner node of  $T$  with left child  $l$ , right child  $r$ , and  
 295 parent  $p$ . We say that  $T'$  is obtained from  $T$  after *left (right) contracting*  $t$  if  $T'$  is the DT  
 296 obtained from  $T$  after removing  $t$  together with all nodes in  $T_r/T_l$  and adding the edge  
 297 between  $p$  and  $l/r$ ; if  $t$  has no parent then no edge is added.

298 We say that  $T$  is a *DT for  $b$* , if  $T$  is a DT for  $\text{exam}(b)$  that uses only the features in  $\text{feat}(b)$ .  
 299 We say that an inner node  $t \in V(T)$  is *left (right) redundant* in  $T$  if  $\text{feat}(t) \in \text{feat}(\text{anc}^L(t))$   
 300 ( $\text{feat}(t) \in \text{feat}(\text{anc}^R(t))$ ). We say that  $t$  is redundant if it is either left redundant or right  
 301 redundant. Intuitively, a node  $t$  is left (right) redundant if all examples that end up at  $t$ ,  
 302 i.e., the examples in  $E_T(t)$ , go the left (right) child of  $t$  in  $T$ . Therefore, if  $t$  is left (right)  
 303 redundant in  $T$ , then the tree obtained after left (right) contracting  $t$  is still a DT.

304 We say that  $T$  is a *DT template* for  $b$  if  $T$  is a DT for  $\text{exam}(b)$  that can additionally  
 305 use the future features in  $I_{[k]}$ . Here, we assume that a future feature  $f_{L'} \in I_{[k]}$  for some  
 306  $L' \subseteq [k]$  is 1 at an example  $e \in \text{exam}(b)$  if  $\lambda_b(e) \in L'$  and otherwise it is 0. We say that  
 307 a DT template is *complete* if it does not use any features in  $I_{[k]}$ , otherwise we say that it  
 308 is *incomplete*. Informally, the role of the future features in a DT template is to provide  
 309 spaceholders for the features in  $\text{feat}(E) \setminus \text{feat}(b)$ . Because all of those features behave the  
 310 same w.r.t. to examples in  $\text{exam}(b)$  having the same label, they can be charactericed by the  
 311 set of labels for which those features are 1. Let  $T$  be a DT template for  $b$  and let  $t \in V(T)$ .

312 We denote by  $A_T(t)$  (or short  $A(t)$ ) if  $T$  is clear from the context) the set of *filtered labels* for  $t$ ,  
 313 i.e.,  $A(t) = (\bigcap_{f_{L'} \in \text{feat}(\text{anc}_L(t)) \cap I_{[k]}} \overline{L'}) \cap (\bigcap_{f_{L'} \in \text{feat}(\text{anc}_R(t)) \cap I_{[k]}} L')$ . Informally,  $A(t)$  is the set  
 314 of all labels  $l \in [k]$  such that an example  $e$  with label  $l$  would end up at  $t$ , if only the effect of  
 315 the future features on the path to  $t$  is considered. We say that  $t$  with  $f_{L'} = \text{feat}(t) \in I_{[k]}$  is  
 316 *left (right) redundant* in  $T$  if  $A(t) \subseteq L'$  ( $A(t) \subseteq \overline{L'}$ ). We say that  $t$  is *redundant* if it is either  
 317 left redundant or right redundant. Intuitively,  $t$  is left (right) redundant if all examples that  
 318 can reach  $t$  (considering the influence of the future features only) end up in the left (right)  
 319 child of  $t$ . This also implies that if  $t$  is left (right) redundant, then the DT template obtained  
 320 after left (right) contracting  $t$  is equivalent with  $T$  (all examples end up in the same leaves).  
 321 Finally, let us extend the definition  $E_T(t)$  from DTs to DT templates. That is, for a DT  
 322 template  $T$  for a node  $b$ , a node  $t \in V(T)$ , and a set of examples  $E' \subseteq \text{exam}(b)$ , we denote  
 323 by  $E_T(E', t)$  (or  $E_T(t)$  if  $E' = \text{exam}(b)$ ) the set of examples  $e \in E'$  with  $\lambda_b(e) \in A(t)$  and  
 324  $e \in E'[\tau(t)]$ , where  $\tau(t)$  is the assignment of the features in  $\text{feat}(b)$  along the path from the  
 325 root of  $T$  to  $t$ .

define  $\tau$  in prelims

326 We say that  $T$  is a *DT skeleton* for  $b$  if  $T$  is a DT that can only use features in  $F_{[k]} \cup I_{[k]}$ .  
 327 Note that because of the features  $F_{[k]}$ , whose behaviour w.r.t. the examples in  $\text{exam}(b)$  is  
 328 not defined, the behaviour w.r.t. the examples in  $\text{exam}(b)$  of such a DT skeleton is not  
 329 necessarily defined. Nevertheless, the behaviour of a feature  $f_l$  in  $F_{[k]}$  is well-defined w.r.t.  
 330 to the examples in  $\text{exam}(E) \setminus \text{exam}(b)$ , i.e., it behaves the same as any feature in  $\text{feat}(b)$   
 331 with label  $l$ . Intuitively, DT skeletons are obtained from DT templates after replacing every  
 332 feature  $f$  in  $\text{feat}(b)$  with the forgotten feature  $f_{\lambda_b(f)}$ . This allows us to further compress the  
 333 information contained in DT templates, while still keeping the information about how the  
 334 DT template behaves w.r.t. future examples in  $E$ . In particular, DT skeletons will form the  
 335 main information stored by our records.

336 Let  $T$  be a DT skeleton and  $t \in V(T)$ . Similarly as we did for DT templates, we say that  
 337  $T$  is *complete* if it uses no future features and otherwise we say that it is incomplete. We say  
 338 that an inner node  $t$  with  $f_l = \text{feat}(t) \in F_{[k]}$  is *left (right) redundant* in  $T$  if  $f_l \in \text{feat}(\text{anc}^L(t))$   
 339 ( $f_l \in \text{feat}(\text{anc}^R(t))$ ). Similarly, as for DT (templates), if  $t$  with  $\text{feat}(t) \in F_{[k]}$  is left (right)  
 340 redundant, then we can left (right) contract  $t$  without changing the properties of  $T$ .

341 Let  $T$  be a DT (skeleton/template). Then, we denote by  $r(T)$  the DT obtained from  $T$   
 342 after left (right) contracting every left (right) redundant node of  $T$ . The following lemma  
 343 shows that  $r(T)$  is well-defined, i.e., the order in which the left (right) contractions are  
 344 performed does not influence the result.

345 ▶ **Lemma 7.** *Let  $T$  be a DT (skeleton/template), let  $t \in V(T)$  be a left (right) redundant node  
 346 in  $T$ , and let  $T'$  be the DT (skeleton/template) obtained from  $T$  after left (right) contracting  
 347  $t$ . Then, a node  $t' \in V(T')$  is left (right) redundant in  $T'$  if and only if  $t'$  is left (right)  
 348 redundant in  $T$ .*

349 **Proof.** Clearly, if  $t'$  is left (right) redundant in  $T'$ , then the same is true in  $T$ ; this is because  
 350 if  $t''$  is a left (right) ancestor of  $t'$  in  $T'$ , then the same holds in  $T$ . So suppose that  $t'$  is  
 351 left (right) redundant in  $T$ . If  $\text{feat}(t')$  is a real or forgotten feature, then  $t'$  is left (right)  
 352 redundant in  $T$  because of some left (right) ancestor  $t_A$  of  $t'$  in  $T$  with  $\text{feat}(t_A) = \text{feat}(t')$ .  
 353 If  $t_A \neq t$ , then  $t'$  is also left (right) redundant in  $T'$  (because  $t_A$  is also in  $T'$ ). Otherwise,  
 354  $t_A = t$  and therefore  $t$  must also be left (right) redundant in  $T$ ; because otherwise  $t'$  was  
 355 removed when  $t$  was contracted. Therefore,  $t$  is left (right) redundant in  $T$  because of some  
 356 left (right) ancestor  $t'_A$  of  $t$  in  $T$  with  $\text{feat}(t'_A) = \text{feat}(t) = \text{feat}(t')$ , which implies that  $t'$  is  
 357 left (right) redundant in  $T'$  because of  $t'_A$ .

358 If, on the other hand,  $\text{feat}(t')$  is a future feature  $f_{L'}$ , then  $A_T(t') \subseteq \overline{L'}$  ( $A_T(t') \subseteq L'$ ).  
 359 We will show that  $A_T(t') = A_{T'}(t')$ , which shows that  $t'$  remains left (right) redundant in

360 This clearly holds if  $\text{feat}(t)$  is not a future feature. So suppose that  $\text{feat}(t) = f_L$ . Then,  
 361 because  $t$  is left (right) redundant in  $T$  (because otherwise  $t'$  would have been removed from  
 362  $T$  when contracting  $t$ ), we have that  $A_T(t) \subseteq \bar{L}$  ( $A_T(t) \subseteq L$ ). Therefore,  $A_T(t) = A_T(t) \cap \bar{L}$   
 363 ( $A_T(t) = A_T(t) \cap L$ ), which shows that  $t$  has no influence on  $A_T(t')$  and therefore implies  
 364 that  $A_T(t') = A_{T'}(t')$ . ◀

365 We now show that  $r(T)$  shares certain properties with  $T$ . In particular, the first observation  
 366 shows that if  $T$  is a DT template for  $b$ , then so is  $r(T)$ .

367 ▶ **Observation 8.** *Let  $T$  be a DT template for  $b$ , then so is  $r(T)$ .*

368 **Proof.** It suffices to show that if  $t$  is left (right) redundant in  $T$  and  $e$  is in  $E_T(t)$ , then  $e$   
 369 goes to the left (right) child of  $t$  in  $T$ . If  $\text{feat}(t) \in \text{feat}(b)$ , then  $t$  is left (right) redundant  
 370 because of some left (right) ancestor  $t'$  with  $\text{feat}(t') = \text{feat}(t)$ . Moreover, because  $e \in E_T(t)$ ,  
 371  $e$  went to the left (right) child of  $t'$  and therefore  $e$  goes to the left (right) child of  $t$  (because  
 372  $\text{feat}(t) = \text{feat}(t')$ ). If, on the other hand,  $\text{feat}(t)$  is some future feature  $f_L$ , then  $A(t) \subseteq \bar{L}$   
 373 ( $A(t) \subseteq L$ ) and because  $e \in E_T(t)$ , also  $\lambda_b(e) \in A(t)$ . Therefore,  $e$  goes to the left (right)  
 374 child of  $t$ . ◀

375 The second observation shows the similarity in behaviour of  $T$  and  $r(T)$  with respect to  
 376 future examples in  $E \setminus \text{exam}(b)$ .

377 ▶ **Observation 9.** *Let  $T$  be a DT (skeleton/template) for  $b$ , and let  $e$  be an example in  
 378  $E \setminus \text{exam}(b)$  that is correctly classified by  $T$ . Then,  $e$  is also correctly classified by  $r(T)$ .*

379 **Proof.** The proof is very similar to the proof of Observation 8. That is, again it suffices to  
 380 show that if  $t$  is left (right) redundant in  $T$  and  $e$  goes to  $t$ , then  $e$  goes to the left (right) child  
 381 of  $t$  in  $T$ . The proof is essentially the same as the proof in Observation 8 for the case that  
 382  $\text{feat}(t)$  is a real feature or a future feature. Moreover, if  $\text{feat}(t)$  is a forgotten feature  $f_L$ , then  
 383  $t$  is left (right) redundant because of some left (right) ancestor  $t'$  with  $\text{feat}(t') = \text{feat}(t) = f_L$ .  
 384 Moreover, because  $e$  goes to  $t$ ,  $e$  went to the left (right) child of  $t'$  and therefore  $e$  goes to  
 385 the left (right) child of  $t$  (because  $e$  behaves in the same way w.r.t. every feature in  $V_b$  that  
 386 has the same label). ◀

387 Before we define our records and their semantics, we first show a bound on the number  
 388 of DT skeletons (and the time to enumerate those) as this will allow us to obtain a similar  
 389 bound for the number of records. We say that  $T$  is *reduced* if  $r(T) = T$ .

390 ▶ **Observation 10.** *Let  $T$  be a reduced DT skeleton whose forgotten features use a set of at  
 391 most  $k_F$  labels and whose future features use a set of at most  $k_I$  labels. Then,  $T$  has height  
 392 at most  $k_F + k_I + 1$  and size at most  $2^{k_F+k_I+1}$ .*

393 **Proof.** Consider a root-to-leaf path  $P$  in  $T$ . Then, every forgotten feature appears at most  
 394 once on  $P$ ; because the second occurrence of such a feature would necessarily be redundant.  
 395 Therefore,  $P$  can contain at most  $k_F$  forgotten features. Similarly,  $P$  can contain at most  
 396  $k_I$  future features, since otherwise one of the future features on  $P$  would be redundant.  
 397 Therefore,  $T$  has height at most  $k_F + k_I + 1$  and therefore size at most  $2^{k_F+k_I+1}$ . ◀

398 We obtain the following corollary as a special case.

399 ▶ **Corollary 11.** *Let  $T$  be a reduced DT skeleton for a node  $b \in V(B)$ . Then,  $T$  has height at  
 400 most  $2k + 1$  and size at most  $2^{2k+1}$ .*

401 ► **Observation 12.** *The are at most  $(k_F + 2^{k_I})^{2^{k_F+k_I+2}+1}$  reduced DT skeletons whose  
402 forgotten features use a set of at most  $k_F$  labels and whose future features use a set of at  
403 most  $k_I$  labels. Moreover, those can be enumerated in time  $\mathcal{O}((k_F + 2^{k_I})^{2^{k_F+k_I+2}+1})$ .*

404 **Proof.** Because of Observation 10 such a DT skeleton has height at most  $k_F + k_I + 1$  and  
405 size at most  $2^{k_F+k_I+1}$ . Therefore, the statement of the lemma follows from Lemma 1 by  
406 setting  $a = k_F + 2^{k_I}$  and  $s = 2^{k_F+k_I+1}$ . ◀

407 We obtain the following corollary as a special case.

408 ► **Corollary 13.** *The are at most  $(k + 2^k)^{2^{2k+2}+1}$  reduced DT skeletons for a node  $b \in V(B)$   
409 and those can be enumerated in time  $\mathcal{O}((k + 2^k)^{2^{2k+2}+1})$ .*

410 Let  $T$  be a DT (template/skeleton) using only features in  $\text{feat}(E) \cup F_L \cup \text{SoIFL}$  for some  
411 set  $L$  of labels (usually  $L = [k]$ ). A *feature relabeling* is a function  $\alpha : \text{feat}(E) \cup F_L \rightarrow F_{L'} \cup I_{L'}$ ,  
412 where  $L'$  is some set of labels (usually  $L' = L$ ). With a slight abuse of notation, we denote  
413 by  $\alpha(T)$ , the decision tree obtained after relabeling all features used by  $T$  according to  $\alpha$ ,  
414 i.e.,  $\alpha(T)$  is obtained from  $T$  after replacing the feature assignment function  $\text{feat}_T(t)$  for  $T$   
415 with the function  $\text{feat}_{\alpha(T)}(t)$  defined by setting  $\text{feat}_{\alpha(T)}(t) = \alpha(\text{feat}_T(t))$  if  $\alpha$  is defined for  
416  $\text{feat}(t)$  and  $\text{feat}_{\alpha(T)}(t) = \text{feat}_T(t)$ , otherwise. We say that two feature relabellings  $\alpha_1$  and  $\alpha_2$   
417 are *compatible* if they agree on their shared domain.

418 We denote by  $\alpha_b^s$  the *standard feature relabelling* for  $b$ , i.e., the function  $\alpha_b^s : \text{feat}(b) \rightarrow F_{[k]}$   
419 defined by setting  $\alpha_b^s(f) = f_{\lambda_b(f)}$  for every  $f \in \text{feat}(b)$ .

420 We now show an important property on the interchangeability of feature relabelings and  
421 reductions. That is, we show in Lemma 15 below that the effect of any sequence of feature  
422 relabellings and reductions that ends with the reduction operation ( $r()$ ) is the same as the  
423 effect of the sequence that contains the same relabelling operations followed by one reduction  
424 operation at the end. To show this property, we need the following auxiliary lemma.

425 ► **Lemma 14.** *Let  $T$  be a DT (template/skeleton) for a node  $b \in V(B)$  and let  $\alpha$  be a  
426 feature relabelling. If a node  $t \in V(T)$  is left (right) redundant in  $T$ , then it is also left (right)  
427 redundant in  $\alpha(T)$ .*

428 **Proof.** We distinguish the following two cases. If  $\text{feat}(t) \in \text{feat}(b) \cup F_{[k]}$ , then  $t$  is left (right)  
429 redundant in  $T$  because of some left (right) ancestor  $t'$  of  $t$  in  $T$  with  $\text{feat}(t) = \text{feat}(t')$ .  
430 Because  $\alpha(\text{feat}(t)) = \alpha(\text{feat}(t'))$ , we obtain that  $t$  is also left (right) redundant in  $\alpha(T)$   
431 because of  $t'$ . If, on the other hand,  $\text{feat}(t) \in I_{[k]}$ , then  $t$  is left (right) redundant in  $T$   
432 because of some set  $A$  of ancestors  $t_A$  with  $\text{feat}(t_A) \in I_{[k]}$ . Because the domain of  $\alpha$  does  
433 not include future features, it follows that  $\alpha$  does not change the feature assignment for  $t$   
434 nor for its ancestors in  $A$ , and therefore  $t$  is also left (right) redundant in  $\alpha(T)$ . ◀

435 ► **Lemma 15.** *Let  $T$  be a DT (template/skeleton) and let  $\alpha$  be a feature relabelling. Then,  
436  $r(\alpha(T)) = r(\alpha(r(T)))$ .*

437 **Proof.** Let  $T'$  be the DT (template/skeleton) obtained from  $\alpha(T)$  after left (right) contracting  
438 every node  $t$  that is left (right) redundant in  $T$ ; note that such a node  $t$  is also left (right)  
439 redundant in  $\alpha(T)$  because of Lemma 14. Then,  $T' = \alpha(\text{red}(T))$  and moreover because of  
440 Lemma 7 (and using the fact that every node  $t$  that is left (right) redundant in  $T$  is so  
441 in  $\alpha(T)$ ), a node  $t \in V(T')$  is left (right) redundant in  $T'$  if and only if it is so in  $\alpha(T)$ .  
442 Therefore, a node  $t$  is left (right) redundant in  $\alpha(T)$  if and only if it is left (right) redundant  
443 in  $T$  or in  $\alpha(r(T)) = T'$ , which shows that  $r(\alpha(T)) = r(\alpha(r(T)))$ . ◀

444 We are now ready to define the records and their semantics. A *record* for  $b$  is a pair  
 445  $(T, s)$  such that  $T$  is a reduced decision tree skeleton for  $b$  and  $s$  is a natural number. We  
 446 say that a record  $(T, s)$  is *semi-valid* for  $b$  if there is a (reduced) DT template  $T'$  for  $b$  such  
 447 that  $r(\alpha_b^s(T')) = T$  and  $s = |V(T') \setminus V(T)|$ . We say that a record  $(T, s)$  is *valid* for  $b$  if  $s$  is  
 448 the minimum number such that  $(T, s)$  is semi-valid. We denote by  $\mathcal{R}(b)$  the set of all valid  
 449 records for  $b$ . The following corollary follows immediately from Corollary 13.

450 ▶ **Corollary 16.**  $|\mathcal{R}(b)| \leq (k + 2^k)^{2^{2k+2}+1}$

451 Note that  $E$  has a DT of size at most  $s$  if and only if  $\mathcal{R}(r)$  for the root  $r$  of  $B$  contains a  
 452 record  $(T, s)$  such that  $T$  is complete.

### 453 3.3 Proof to the Main Result

454 We will now show that we can compute  $\mathcal{R}(b)$  for every of the 3 node types of a nice  $k$ -NLC  
 455 expression tree provided that  $\mathcal{R}(c)$  has already been computed for every child  $c$  of  $b$ .

456 ▶ **Lemma 17** (leaf node). *Let  $b \in V(B)$  be a leaf node. Then  $\mathcal{R}(b)$  can be computed in time  
 457  $\mathcal{O}(k(1 + 2^k)^{2^{k+3}+1})$ .*

458 **Proof.** Let  $i(v)$  be the initial  $k$ -graph associated with  $b$ . If  $v$  is a feature, then  $\mathcal{R}(b)$  contains  
 459 all records  $(T, 0)$  such that  $T$  is a reduced DT skeleton for  $b$  using only the features in  
 460  $\{f_{\lambda(v)}\} \cup I_{[k]}$ . The correctness in this case follows because  $V_b$  contains no examples and  
 461 therefore every reduced DT skeleton constitutes a valid record for  $b$ . Moreover, the run-time  
 462 follows from Observation 12, since the time required to enumerate all those reduced DT  
 463 skeletons is at most  $\mathcal{O}((1 + 2^k)^{2^{k+3}+1})$ .

464 If, on the other hand  $v$  is an example, then  $\mathcal{R}(b)$  contains all records  $(T, 0)$  such that  $T$   
 465 is a reduced DT skeleton for  $b$  using only the features in  $I_{[k]}$  and which correctly classify  $v$ .  
 466 Because of Observation 12, those can be enumerated in time  $\mathcal{O}((1 + 2^k)^{2^{k+3}+1})$  and checking  
 467 for each of those whether it correctly classifies  $v$  can be achieved in time  $\mathcal{O}(k)$  because of  
 468 Observation 10. ◀

469 ▶ **Lemma 18** (join node). *Let  $b \in V(B)$  be a join node. Then  $\mathcal{R}(b)$  can be computed in time  
 470  $\mathcal{O}(2^{3k+1}(2k + 2^k)^{2^{3k+2}+1})$ .*

todo: simplify the  
run-time  
expression

471 **Proof.** Let  $b_L$  and  $b_R$  be the left and right child of  $b$  in  $B$ , respectively. Let  $M_b$  be the  
 472 join matrix for the node  $b$ , i.e.,  $M_b$  is a  $k \times k$  binary matrix. For every label  $i \in [k]$ , let  
 473  $A_{i,*} = \{j \in [k] \mid M_b[i, j] = 1\}$  and  $A_{*,i} = \{j \in [k] \mid M_b[j, i] = 1\}$ .

474 To distinguish between forgotten features from the left and the right subtree, we introduce  
 475 the left  $i_L$  and the right version  $i_R$  for every label  $i \in [k]$ . With a slight abuse of notation,  
 476 we also denote by  $[k_L]$  be the set  $\{1_L, \dots, k_L\}$  of (left) labels and we denote by  $[k_R]$  be the  
 477 set  $\{1_R, \dots, k_R\}$  of (right) labels.

478 To compute the set  $\mathcal{R}(b)$  of valid records for  $b$ , we first enumerate all reduced DT skeletons  
 479  $T$  using features in  $[k_L] \cup [k_R] \cup I_{[k]}$ . Because of Observation 12, those can be enumerated in  
 480 time  $\mathcal{O}((2k + 2^k)^{2^{3k+2}+1})$ . For every such reduced DT skeleton  $T$ , we now do the following in  
 481 order to decide whether  $T$  gives rise to a valid record for  $b$ . Let  $\alpha_{LR \rightarrow} : F_{[k_L]} \cup F_{[k_R]} \rightarrow F_{[k]}$   
 482 be the feature relabeling that relabels every (left/right) feature  $f_{i_H} \in F_{[k_L]} \cup F_{[k_R]}$  (for some  
 483  $H \in \{L, R\}$ ) to its original feature  $f_i$ .

484 Let  $\alpha_L : F_{[k_R]} \rightarrow I_{[k]}$  be the feature relabeling that relabels every forgotten feature  
 485  $f_{i_R} \in F_{[k_R]}$  to the future feature  $f_{A_{*,i}}$ . Let  $T_L$  be the reduced DT skeleton obtained from  $T$   
 486 after applying the relabelling using  $\alpha_L$  followed by  $\alpha_{LR \rightarrow}$  and then reducing the resulting  
 487 DT skeleton, i.e.,  $T_L = r(\alpha_{LR \rightarrow}(\alpha_L(T)))$ .

488     Similarly, let  $\alpha_R : F_{[k]_L} \rightarrow I_{[k]}$  be the feature relabeling that relabels every forgotten  
 489     feature  $f_{i_L} \in F_{[k]_L}$  to the future feature  $f_{A_{i,*}}$ . Let  $T_R$  be the reduced DT skeleton obtained  
 490     from  $T$  after applying the relabelling using  $\alpha_R$  followed by  $\alpha_{LR \rightarrow}$  and then reducing the  
 491     resulting DT skeleton, i.e.,  $T_R = r(\alpha_{LR \rightarrow}(\alpha_R(T)))$ .

492     Let  $\hat{T} = r(\alpha_{LR \rightarrow}(T))$  and  $\hat{s} = |V(T) \setminus V(\hat{T})|$ . We now check whether there are records  
 493      $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$ . If not we discard  $T$  and if yes, then we add the  
 494     record  $(\hat{T}, s_L + s_R + \hat{s})$  to  $\mathcal{R}(b)$ . This completes the description about how the records  
 495      $\mathcal{R}(b)$  are computed. Moreover, the run-time for computing  $\mathcal{R}(b)$  can be obtained as follows.  
 496     First, because of Observation 12, we can enumerate all reduced DT skeletons  $T$  in time  
 497      $\mathcal{O}((2k + 2^k)^{2^{3k+2}+1})$ . Moreover, computing  $\hat{T}$  and  $\hat{s}$  can be done in time  $\mathcal{O}(|T|) = \mathcal{O}(2^{3k+1})$   
 498     (using Observation 10). Finally, computing  $T_L$  and  $T_R$  and checking the existence of the  
 499     records  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$  can be achieved in time  $\mathcal{O}(|T|) = \mathcal{O}(2^{3k+1})$ ;  
 500     here we assume that the records in  $\mathcal{R}(b)$  are stored in an array whose key is  $\hat{T}$ . Therefore,  
 501     we obtain  $\mathcal{O}(|T|(2k + 2^k)^{2^{3k+2}+1}) = \mathcal{O}(2^{3k+1}(2k + 2^k)^{2^{3k+2}+1})$  as the total run-time for  
 502     computing  $\mathcal{R}(b)$ .

503     We now show the correctness of our construction for  $\mathcal{R}(b)$ , i.e., we have to show that  
 504     a record is valid if and only if we have added such a record according to our construction  
 505     above. For this it suffices to show that a record is semi-valid if and only if we have added  
 506     such a record according to our construction above. This is because, a valid record  $(T, s)$  can  
 507     be obtained from the set of all semi-valid records  $(T, s')$ , where  $s$  is the minimum  $s'$  among  
 508     all semi-valid records for  $T$ .

509     Towards showing the forward direction, suppose that  $(\hat{T}, s)$  is a semi-valid record for  $b$ .  
 510     Therefore, there is a DT template  $T'$  for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$  and  $s = |V(T') \setminus V(T)|$ .

511     Let  $\alpha_{\rightarrow R} : F_{[k]} \rightarrow F_{[k_R]}$  ( $\alpha_{\rightarrow L} : F_{[k]} \rightarrow F_{[k_L]}$ ) be the feature relabeling that relabels  
 512     every forgotten feature  $f_i \in F_{[k]}$  to its corresponding forgotten feature in  $[k_R]$  ( $[k_L]$ ), i.e.,  
 513      $\alpha_{\rightarrow R}(i) = i_R$  ( $\alpha_{\rightarrow L}(i) = i_L$ ) for every  $i \in [k]$ .

514     Let  $T = r(\alpha_{\rightarrow R}(\alpha_{b_R}^s(\alpha_{\rightarrow L}(\alpha_{b_L}^s(T')))))$  and let  $\hat{s} = |V(T) \setminus V(\hat{T})|$ . Because  $\alpha_b^s = \alpha_{LR \rightarrow} \circ$   
 515      $\alpha_{\rightarrow R} \circ \alpha_{b_R}^s \circ \alpha_{\rightarrow L} \circ \alpha_{b_L}^s$ , we obtain from Lemma 15 that  $\hat{T} = r(\alpha_{LR \rightarrow}(T))$ .

516     Let  $T_L = r(\alpha_{LR \rightarrow}(\alpha_L(T)))$  and  $T_R = r(\alpha_{LR \rightarrow}(\alpha_R(T)))$ . It remains to show that there  
 517     are  $s_L$  and  $s_R$  with  $s = s_L + s_R + \hat{s}$  such that  $(T_L, s_L) \in \mathcal{R}(b_L)$  and  $(T_R, s_R) \in \mathcal{R}(b_R)$ .

518     Let  $T'_L = r(\alpha_L(\alpha_{\rightarrow R}(\alpha_{b_R}^s(T'))))$  and  $T'_R = r(\alpha_R(\alpha_{\rightarrow L}(\alpha_{b_L}^s(T'))))$ . Note that  $T'_H$  is a DT  
 519     template for  $b_H$  because so is  $T'$ .

520     Note that  $T_L = r(\alpha_{b_L}^s(T'_L))$  because of Lemma 15 and the observation that the sequence  
 521      $\alpha_{LR \rightarrow} \circ \alpha_L \circ \alpha_{\rightarrow R} \circ \alpha_{b_R}^s \circ \alpha_{\rightarrow L} \circ \alpha_{b_L}^s$  of relabellings to obtain  $T_L$  via  $T$  has the same total  
 522     effect as the sequence  $\alpha_{b_L}^s \circ \alpha_L \circ \alpha_{\rightarrow R} \circ \alpha_{b_R}^s$  of relabellings to obtain  $T_L$  via  $T'_L$ . Using a  
 523     similar argument, we obtain that  $T_R = r(\alpha_{b_R}^s(T'_R))$ . Let  $s_H = |V(T'_H) \setminus V(T_H)|$  for every  
 524      $H \in \{L, R\}$ . Then,  $T'_H$  shows that  $(T_H, s_H)$  is a semi-valid record for  $b_H$ .

525     It remains to show that  $s_L + s_R + \hat{s} = s$ . Note first that  $s = |V(T') \setminus V(\hat{T})| =$   
 526      $|V(T') \setminus V(T)| + |V(T) \setminus V(\hat{T})| = |V(T') \setminus V(T)| + \hat{s}$  and it therefore suffices to show that  
 527      $s_L + s_R = |V(T') \setminus V(T)|$ . Towards showing this, let  $t$  be a node in  $|V(T') \setminus V(T)|$ . First note  
 528     that  $\text{feat}_{T'}(t) \in \text{feat}(b_H)$  for some  $H \in \{L, R\}$ , because all nodes with future features in  $T'$   
 529     are also in  $T$ . Therefore,  $t$  is in  $V(T'_H) \setminus V(T_H)$ , which shows that  $t$  is either in  $V(T'_L) \setminus V(T_L)$   
 530     or in  $V(T'_R) \setminus V(T_R)$ , as required.

531     Towards showing the reverse direction, suppose that our construction adds the record  
 532      $(\hat{T}, s_L + s_R + \hat{s})$  and let  $T$ ,  $T_L$ , and  $T_R$  be as defined in the construction. Recall that:

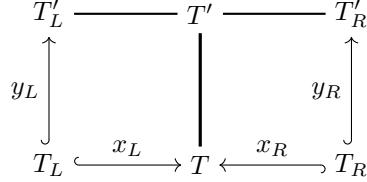

- 533       ■  $T$  is reduced and  $\hat{T} = r(\alpha_{LR \rightarrow}(T))$ ,
- 534       ■  $T_L = r(\alpha_L(T))$  and  $(T_L, s_L)$  is semi-valid for  $b_L$ ,
- 535       ■  $T_R = r(\alpha_R(T))$  and  $(T_R, s_R)$  is semi-valid for  $b_R$ .

536 Let  $T'_L$  be the reduced DT template for  $b_L$  such that  $T_L = r(\alpha_{b_L}^s(T'_L))$  and  $s_L =$   
 537  $|V(T'_L) \setminus V(T_L)|$ , which exists because  $(T_L, s_L)$  is semi-valid for  $b_L$ . Similarly, let  $T'_R$  be the  
 538 reduced DT template for  $b_R$  such that  $T_R = r(\alpha_{b_R}^s(T'_R))$  and  $s_R = |V(T'_R) \setminus V(T_R)|$ , which  
 539 exists because  $(T_R, s_R)$  is semi-valid for  $b_R$ .

540 We now show how to construct a witness  $T'$  (from  $T$ ,  $T'_L$ , and  $T'_R$ ) for the semi-validity of  
 541 the record  $(\hat{T}, s_L + s_R + \hat{s})$ , i.e.,  $T'$  is a reduced DT template for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$   
 542 and  $s_L + s_R + \hat{s} = |V(T') \setminus V(\hat{T})|$ .

543 Informally, we obtain  $T'$  from  $T$  after reversing the relabelling and reduction operations  
 544 applied to  $T'_L$  and  $T'_R$  to obtain  $T_L$  and  $T_R$ , respectively; recall that  $T_H = r(\alpha_{b_H}^s(T'_H))$  for  
 545  $H \in \{L, R\}$ . That is, we will reverse the labelling for the nodes in  $T$  and add back the nodes  
 546 to  $T$  that have been removed from  $T'_L$  and  $T'_R$ .

547 Let  $H \in \{L, R\}$ . Because  $T_H$  is obtained from  $T$  by reduction, every node in  $T_H$   
 548 corresponds to a unique node in  $T$ . Therefore, there is an injective function  $x_H : V(T_H) \rightarrow$   
 549  $V(T)$  mapping every node in  $T_H$  to its original node in  $T$ . Similarly, because  $T_H$  is obtained  
 550 from  $T'_H$  by reduction, there is an injective function  $y_H : V(T_H) \rightarrow V(T'_H)$  mapping every  
 551 node in  $T_H$  to its original node in  $T'_H$ . See also Figure 2 for an illustration of these mappings.

■ **Figure 2**

552 In order to obtain  $T'$  from  $T$ , we will essentially need to be able to reverse the reduction  
 553 operation  $T_H = r(\alpha_{b_H}^s(T'_H))$  that has been applied to  $T'_H$  to obtain  $T_H$  for every  $H \in \{L, R\}$ .  
 554 To do so we first need to introduce the so-called plugin operation and notions around this  
 555 operation. We will do so in the next two paragraphs.

556 Let  $D$  and  $D'$  be two DT (templates/skeletons). Let  $P = (d, p_1, \dots, p_\ell, d')$  be the path  
 557 from  $d$  to  $d'$  in  $D$  such that  $d$  is an ancestor of  $d'$  in  $D$ , for some integer  $\ell$ . Moreover,  
 558 let  $e = (p, c)$  be an edge in  $D'$  such that  $p$  is the parent of  $c$  in  $D'$ . We say that the DT  
 559 (template/skeleton)  $D''$  is obtained by *plugging in the path  $P$  into  $D'$  at edge  $e$*  if  $D''$  is  
 560 obtained from  $D'$  by doing the following. For an inner vertex  $p_i$  of  $P$ , let  $D(P, p_i)$  be the  
 561 subtree of  $D$  rooted at the unique child  $c$  of  $p_i$  that is not on  $P$ . Let  $P'$  be the induced subtree  
 562 of  $D$  containing all vertices of  $P$  plus all vertices of  $D(P, p_i)$  for every  $i$  with  $1 \leq i \leq \ell$ . Then,  
 563  $D''$  is obtained from  $D'$  by removing the edge  $e = (p, c)$ , adding  $P'$ , and adding the edge  
 564 from  $p$  to  $p_1$  as well as the edge from  $p_\ell$  to  $c$ . Moreover,  $D''$  inherits all feature assignments  
 565 as well as the left (right) child relation from  $D$  and  $D'$ .

566 The significance of the plugin operation comes from the fact that it allows us to reverse  
 567 the reduction that has been applied to a DT (template/skeleton). For instance, consider  $T'_H$   
 568 and  $T_H$ . Then,  $T_H = r(\alpha_b^s(T'_H))$  and we can use the plugin operation to obtain  $T'_H$  from  $T_H$   
 569 as follows. Let  $z_H : V(T_H) \rightarrow V(T'_H)$  be the injective function mapping every node in  $T_H$  to  
 570 its original node in  $T'_H$ . Then, we first use  $z_H$  to reverse the relabelling given by  $\alpha_b^s(T'_H)$ ,  
 571 i.e., let  $T_H^0$  be the DT template obtained from  $T_H$  by setting  $\text{feat}_{T_H^0}(t) = \text{feat}_{T'_H}(z_H(t))$  for  
 572 every  $t \in V(T_H^0)$ . We now add back the nodes in  $V(T'_H) \setminus V(T_H)$  with the help of our plugin  
 573 operation. In particular, for every edge  $e = (p, c)$  in  $T_H^0$ , where  $p$  is the parent of  $c$  in  $T_H^0$ ,  
 574 let  $P(e)$  be the path in  $T'_H$  between  $z_H(p)$  and  $z_H(c)$ . Let  $T_H^1$  be the DT template obtained  
 575 from  $T_H^0$  after plugin in the path  $P(e)$  into  $T_H^0$  at edge  $e$ , for every edge  $e = (p, c)$  of  $T_H^0$ .

576 Then, it is easy to see that  $T_H^1 = T'_H$ . We will now use the plugin operation to obtain  $T'$   
 577 from  $T'_L$ ,  $T'_R$ ,  $T_L$ , and  $T_R$  in a very similar manner.

578 Our first order of business is to rename all forgotten features in  $T$  to their real features  
 579 as given by  $T'_L$  and  $T'_R$ . That is, for every node  $t$  in  $T$  assigned to a forgotten feature, i.e.,  
 580  $\text{feat}_T(t) \in F_{[k_L]} \cup F_{[k_R]}$ , we do the following. If  $\text{feat}_T(t) \in F_{[k_H]}$  for  $H \in \{L, R\}$ , then  $t$  is also  
 581 in  $T_H$  and hence also in  $T'_H$ . Therefore, we can change  $\text{feat}_T(t)$  to the real feature assigned  
 582 to  $t$  in  $T'_H$ . Let  $T^0$  be the DT obtained from  $T$  after renaming all forgotten features to real  
 583 features in this manner.

584 Consider an edge  $e = (p, c)$  in  $T_L$  such that  $p$  is the parent of  $c$  in  $T_L$ . Then,  $e$  corresponds  
 585 to a path  $P'_L(e)$  between  $y_L(p)$  and  $y_L(c)$  in  $T'_L$ . Similarly,  $e$  corresponds to a path  $P_L(e)$   
 586 between  $x_L(p)$  and  $x_L(c)$  in  $T^0$ .

587 Our next order of business is now to add all nodes to  $T^0$  that have been removed when  
 588 going from  $T'_L$  to  $T_L$  (via the reduction  $r(\alpha_{b_L}^s(T'_L))$ ). To achieve this, we go over every edge  
 589  $e = (p, c)$  of  $T_L$  such that  $p$  is the parent of  $c$  in  $T_L$  and plugin the path  $P'_L(e)$  (from  $T'_L$ )  
 590 into the last edge on the path  $P_L(e)$  (from  $T^0$ ). Let  $T^1$  be the tree obtained from  $T^0$  after  
 591 doing this operation for every edge of  $T_L$ .

592 Consider an edge  $e = (p, c)$  in  $T_R$  such that  $p$  is the parent of  $c$  in  $T_R$ . Then,  $e$  corresponds  
 593 to a path  $P'_R(e)$  between  $y_R(p)$  and  $y_R(c)$  in  $T'_R$ . Similarly,  $e$  corresponds to a path  $P_R(e)$   
 594 between  $x_R(p)$  and  $x_R(c)$  in  $T^1$ . Similarly to above, we now add all nodes to  $T^1$  that have  
 595 been removed when going from  $T'_R$  to  $T_R$  (via the reduction  $r(\alpha_{b_R}^s(T'_R))$ ). To achieve this,  
 596 we go over every edge  $e = (p, c)$  of  $T_R$  such that  $p$  is the parent of  $c$  in  $T_R$  and plugin the  
 597 path  $P'_R(e)$  (from  $T'_R$ ) into the last edge on the path  $P_R(e)$  (from  $T^1$ ). Let  $T'$  be the tree  
 598 obtained from  $T^1$  after doing this operation for every edge of  $T_R$ .

599 We now show that  $T'$  is indeed a witness for the semi-validity of the record  $(\hat{T}, s_L + s_R + \hat{s})$ ,  
 600 i.e.,  $T'$  is a reduced DT template for  $b$  such that  $\hat{T} = r(\alpha_b^s(T'))$  and  $s_L + s_R + \hat{s} = |V(T') \setminus V(\hat{T})|$ .

601 We start by showing that  $T'$  is reduced. First note that because  $T$  is reduced so is  $T^0$ .  
 602 Consider a node  $t \in V(T')$ . If  $\text{feat}_{T'}(t) \in \text{feat}(b_H)$  for some  $H \in \{L, R\}$ , then  $t$  is also in  
 603  $V(T'_H)$ . Therefore, if  $t$  were redundant in  $T'$ , it would also be redundant in  $T'_H$ , which cannot  
 604 be the case because  $T'_H$  is reduced. Moreover, if on the other hand,  $\text{feat}_{T'}(t) \in I_{[k]}$ , then  $t$  is  
 605 in  $T^0$  and therefore cannot be redundant because  $T^0$  is reduced. Therefore,  $T'$  is reduced and  
 606 it obviously only uses features in  $\text{feat}(b) \cup F_{[k]}$ . We show next that  $T'$  is a DT template for  
 607  $b$ , i.e.,  $T'$  classifies all examples in  $\text{exam}(b)$  correctly. Towards showing this, let  $e \in \text{exam}(b)$ ,  
 608 then  $e \in \text{exam}(b_H)$  for some  $H \in \{L, R\}$ . Because  $T'_H$  is a DT template for  $b_H$ , we know  
 609 that  $e$  is correctly classified by  $T'_H$ . Let  $l$  be the leaf in  $T'_H$  that contains  $e$ , i.e.,  $e \in E_{T'_H}(l)$   
 610 and let  $Q$  be the path from the root of  $T'_H$  to  $l$ . Then,  $l$  also exists in  $T'$  and moreover the  
 611 path  $P$  from the root of  $T'$  to  $l$  contains all nodes of  $Q$ . Note furthermore that if a node  $t$  in  
 612  $Q$  has its left/right child on  $Q$ , then the same holds on  $P$ . We will show that  $e$  follows along  
 613 the path  $P$  in  $T'$  and therefore ends up in  $l$ , which shows that  $e$  is correctly classified by  $T'$ .

614 Let  $t$  be a node of  $P$ . If  $t$  is also in  $Q$ , then  $e$  will be send to the child of  $t$  in  $P$ . Otherwise,  
 615  $t$  is either in  $V(T) \setminus V(T_H)$  or  $t$  is in  $T'_{\overline{H}} \setminus T_{\overline{H}}$ , where  $\overline{H} = L$  if  $H = R$  and  $\overline{H} = R$  otherwise.

616 In the former case,  $\text{feat}_{T'}(t) \in I_{[k]}$  or  $\text{feat}_{T'}(t) \in \text{feat}(b_{\overline{H}})$ , which implies that  $t$  behaves  
 617 towards  $e$  in the same manner as some future feature  $f_L \in I_{[k]}$ , i.e., if  $\text{feat}_{T'}(t) \in I_{[k]}$ , then  
 618  $f_L = \text{feat}_{T'}(t)$  and if  $\text{feat}_{T'}(t) \in \text{feat}(b_{\overline{H}})$ , then  $f_L = \alpha_L(\text{feat}_T(t))$ . Moreover,  $t$  is redundant  
 619 in  $\alpha_L(T)$  because of its ancestors in  $T_H$ , i.e., either  $A_{\alpha_L T}(t) \subseteq L$  or  $A_{\alpha_L T}(t) \subseteq \overline{L}$ . Because  
 620 all these ancestors are in  $T_H$  and therefore on  $Q$ ,  $\lambda_{b_L}(e) \in A_{\alpha_L T}(t)$ , which implies that  $e$  is  
 621 send to the non-redundant child of  $t$ . Finally, since  $P$  contains  $l$  it follows that  $P$  contains  
 622 also the non-redundant child of  $t$  in  $\alpha_L(T)$  and therefore  $e$  is send to the child of  $t$  on  $P$ , as  
 623 required.

624 In the latter case, i.e., the case that  $t$  is in  $V(T'_{\overline{H}}) \setminus V(T_{\overline{H}})$ ,  $t$  is redundant in  $\alpha_{b_{\overline{H}}}^s(T'_{\overline{H}})$   
 625 because of some ancestor  $t' \in V(T_{\overline{H}})$  with  $\alpha_{b_{\overline{H}}}^s(feat_{T'}(t)) = \alpha_{b_{\overline{H}}}^s(feat_{T'}(t'))$ . Therefore,  
 626  $feat_{T'}(t')$  behaves in the same manner towards  $e$  as  $feat_{T'}(t)$ , which because  $t'$  is on  $Q$   
 627 (because  $t' \in V(T_{\overline{H}})$ ) implies that  $e$  is send to the (non-redundant) child of  $t$  on  $P$ .

628 It remains to show that  $\hat{T} = r(\alpha_b^s(T'))$  and  $s_L + s_R + \hat{s} = |V(T') \setminus V(\hat{T})|$ . Towards  
 629 showing this, we first show that  $T = r(\alpha_{T' \rightarrow T}(T'))$ , where  $\alpha_{T' \rightarrow T} = \alpha_{\rightarrow L} \circ \alpha_{b_R}^s \circ \alpha_{\rightarrow L} \circ \alpha_{b_L}^s$ .  
 630 In other words, we need to show that the set of redundant nodes in  $\alpha_{T' \rightarrow T}(T')$  is equal to  
 631  $V(T') \setminus V(T) = V(T') \setminus V(T^0)$ . Because, as shown above  $T'$  is reduced, it follows that if  
 632 a node  $t$  is redundant  $\alpha_{T' \rightarrow T}(T')$ , then  $t \in feat_{T'}(b_H)$  for some  $H \{L, R\}$ . Because all such  
 633 nodes, i.e., nodes  $t$  in  $T'$  with  $t \in feat_{T'}(b_H)$  are also in  $T'_H$ , we obtain that  $t$  is redundant in  
 634  $\alpha_{T' \rightarrow T}(T')$  if and only if it is redundant in  $\alpha_{b_H}^s(T'_H)$ . Therefore,  $\bigcup_{H \in \{L, R\}} V(T'_H) \setminus V(T_H)$  is  
 635 the set of all redundant nodes in  $\alpha_{T' \rightarrow T}(T')$ , which is equal to  $V(T') \setminus V(T^0)$  by construction  
 636 of  $T'$ , as required. Note that  $|V(T') \setminus V(T^0)| = s_L + s_R$  because of the construction of  $T'$ .  
 637 Now, because  $\hat{T} = r(\alpha_{LR \rightarrow T}(T))$  and  $\alpha_b^s = \alpha_{LR \rightarrow} \circ \alpha_{T' \rightarrow T}$ , we obtain from Lemma 15 that  
 638  $\hat{T} = r(\alpha_b^s(T'))$ . Finally, because  $|V(T') \setminus V(T^0)| = s_L + s_R$  and  $|V(T^0) \setminus V(\hat{T})| = \hat{s}$ , it follows  
 639 that  $|V(T') \setminus V(\hat{T})| = s_L + s_R + \hat{s}$ , as required. ◀

640 ▶ **Lemma 19** (relabel node). *Let  $b \in V(B)$  be relabel node. Then  $\mathcal{R}(b)$  can be computed in  
 641 time  $\mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$ .*

642 **Proof.** Let  $b_C$  be the unique child of  $b$  in  $B$ . Let  $R$  be the mapping of  $[k]$  to itself that  
 643 represent the node  $b$ . Moreover, since we are considering a *nice* NLC-expression we can  
 644 assume  $R$  is the identity mapping, i.e.  $R(\ell) = \ell$ , for all values except for a unique element  $i$   
 645 of its domain, i.e.  $R(i) = j$  for some  $j \in [k] \setminus \{i\}$ .

646 We say that a future feature  $A$  is *good* if it does not distinguish between  $i$  and  $j$ , that  
 647 is  $i \in A$  if and only if  $j \in A$ , and *bad* otherwise. Let  $(T_C, s_C)$  be an element of  $\mathcal{R}(b_C)$ . Let  
 648  $p''$  the following relabelling of the DT template  $T_C$ : every feature with label  $i$  is assigned  
 649 to label  $j$  and every future feature with label  $A$  is assigned to the future feature with label  
 650  $A \setminus \{i\}$ .

651 If  $T_C$  has a bad future feature then we do not take any other action. Suppose now  $T_C$   
 652 has only good future features; now let  $T$  be the DT template obtained from  $T_C$  after the  
 653 application of the composition  $r \circ p''$  and let  $s^*$  be the number of nodes that have been  
 654 deleted from  $T_C$  to  $T$ .

655 If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s' \leq s_C + s^*$  then we do  
 656 not take any other action. If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  
 657  $s' > s_C + s^*$  then we replace it with  $(T, s_C + s^*)$ . If there is no record in  $\mathcal{R}(b)$  of the form  
 658  $(T, s')$  for some integer  $s'$  then we add  $(T, s_C + s^*)$  to  $\mathcal{R}(b)$ .

659 Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Consider record  $(T_C, s_C)$   
 660 in  $\mathcal{R}(b_C)$ . In  $\mathcal{O}(k)$  time we check if  $T_C$  all the future features are good. For every such DT  
 661  $T_C$ , there are at most  $2^{2k}$  paths from the root to the leaves and for every of these paths there  
 662 are at most  $k$  nodes for each of the following: feature with label  $i$  and and future feature  
 663 that contains  $i$ . This means  $r \circ p''$  can be done in  $\mathcal{O}(k)$  time. This means to compute  $\mathcal{R}(b)$   
 664 takes  $\mathcal{O}(k|\mathcal{R}(b_C)|) = \mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$  time.

665 Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if  
 666 and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$   
 667 of  $T$  for  $b$ .

668 We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exists a  
 669 record  $(T_C, s_C) \in \mathcal{R}(b_C)$  such that  $T$  is obtained from  $T_C$  after the application of  $r \circ p''$  and

670 let  $s^* = s - s_C$ . By induction  $s_C$  is the minimum amount of nodes that have been deleted  
 671 from a witness  $T'_C$  of  $T_C$  for  $b_C$ . By construction we also know that every future feature of  
 672 both  $T'_C$  and  $T_C$  is good.

673 Denote with  $T'$  the real DT obtained  $T'_C$  after the application of  $r \circ p''$ : note that this  
 674 last reduction does not any node since every future feature of  $T'_C$  is good and there is no  
 675 feature with label  $i$ . To conclude this part of the proof we have to show two things: (i)  $T$  is  
 676 obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a witness of  $T$  for  $b$ .

677 Before proving (i), we describe how  $T$  can be obtained from  $T'$ . Let  $p'''$  be the following  
 678 relabelling of  $T'$ : every real feature that contains  $j$  is assigned to the real feature  $A \cup \{i\}$   
 679 and every other feature is assigned to itself. Then the application of the composition  $p'''$ ,  
 680 the standard reduction and  $r \circ p''$  to  $T'$  is exactly the standard reduction for  $T'$  which then  
 681 result to the DT template  $T$ . By Lemma 20 the score of the standard reduction from  $T'$  to  
 682  $T$  is exactly  $s_C + s^* = s$ .

683 Now we consider statement (ii). First note that  $\text{exam}(b) = \text{exam}(b_C)$ . We show that  
 684 a given example  $e \in \text{exam}(b)$  is correctly classified by  $T'$ . Say that  $e$  goes along a path  $P$   
 685 of  $T'_C$  from the root to a leaf  $\ell$ . We show  $e$  goes along the path  $P$  in  $T'$  as well: every real  
 686 feature has not changed and so  $e$  behaves the same. Since every future feature of  $T'_C$  is good,  
 687 then  $e$  behave the same on the corresponding future feature of  $T'$ .

688 Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum  
 689 number of elements that have been deleted from a witness  $T'$  of  $B$  for  $b$ . In particular, we  
 690 recall that real  $T'$  is a DT for  $b$  with real features and future feature labels in  $\mathcal{P}([k] \setminus \{i\})$ .

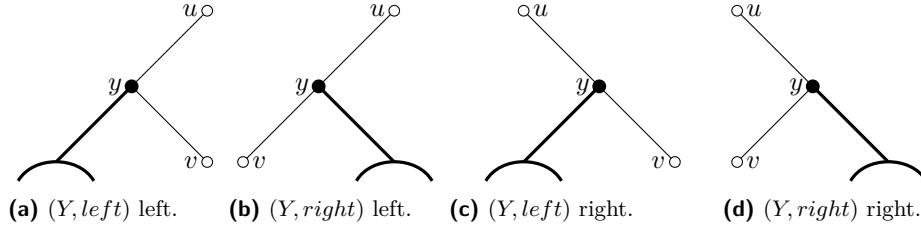

691 We create the real DT  $T'_C$  as the application of  $r \circ p'''$  to  $T'$ , the DT template  $T_C$  as the  
 692 application of the standard reduction to  $T'_C$ . By construction we have  $(T_C, s_C) \in \mathcal{R}(b_C)$ ,  
 693 where  $s_C$  is the number of nodes that have been removed from  $T'_C$  to  $T_C$ . Note that  $T_C$  has  
 694 only good future features. Finally we note that  $T$  is obtained from  $T_C$  by the application of  
 695  $r \circ p''$ . ◀

### 696 3.4 Formal Definition of Records and Preliminary Results

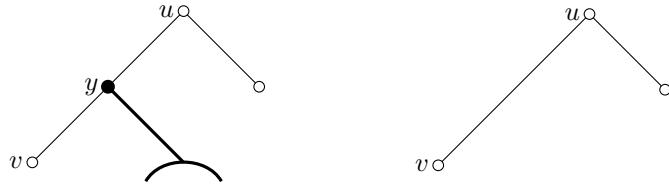

697 We start off with some definitions. We say an edge is a *left (right) edge* of a subcubic rooted  
 698 tree if it connects a non-leaf node with his left (resp. right) child. Let  $Y$  be a rooted subcubic  
 699 tree and  $S \in \{\text{left}, \text{right}\}$ , then we say the pair  $(Y, S)$  is a *single pair* if the root of  $Y$  has at  
 700 most one child and the side  $S$  indicates whether the edge from the root is either a left or  
 701 right edge. Moreover, we say that  $(Y, S)$  is single pair in a subcubic rooted tree  $T$  if  $Y$  is a  
 702 maximal subtree of  $T$  and in  $Y$  the root have at most the  $S$  child. Note that when tree of a  
 703 single pair is made of just a node, the side is not relevant.

704 Now we can define two operations on subcubic rooted trees and single pairs. We say that  
 705 we *plug in* a single pair  $(Y, S)$  in a left (right) edge  $uv$  as follows: we make the root  $y$  of  $Y$  the  
 706 left (right) child of  $u$ ,  $Y \setminus \{y\}$  to be the  $S$  subtree of  $y$  and  $v$  to be the  $H \in \{\text{left}, \text{right}\} \setminus S$   
 707 child of  $y$ . See Figure 3 for the corresponding drawings. Note after a plug in of a single pair  
 708 in an edge, the node  $v$  belongs in the same side of the subtree rooted at  $u$  as it was before  
 709 the plug in.

710 Let  $(Y, S)$  be a single pair in a rooted subcubic tree  $T$ , then we *remove*  $(Y, S)$  from  $T$  as  
 711 follows. Let  $y$  be the root of  $Y$ . If  $y$  is the root of  $T$ , then we obtain an empty tree. If  $y$  is a  
 712 leaf node of  $T$ , then we obtain  $T - y$ . Otherwise let  $y$  be a non-root and non-leaf node, let  $u$   
 713 be the parent of  $y$  and  $v$  be the child of  $y$  that is not in  $V(Y)$ , then we consider the tree  
 714 obtained from  $T$  after replacing  $y$  with  $v$  as the child of  $u$  and deleting  $Y$ . See Figure 4 for  
 715 an example.

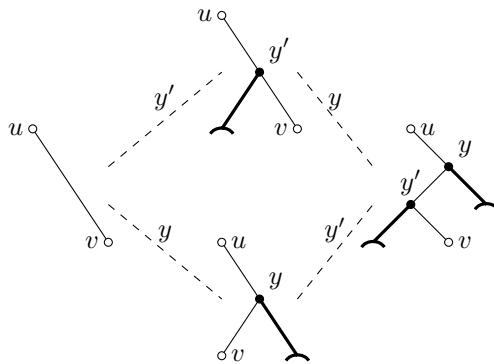

**Figure 3** The drawings describe the plug in operation in the different four cases. The bold part highlight the single pair  $(Y, S)$ .

**Figure 4** The drawing describe an example of the remove operation: a single pair  $(Y, \text{right})$  is removed from a subcubic rooted tree. The bold part highlight the single pair  $(Y, S)$ .

716 It is clear from the four different plug in cases that if we want to plug in two pairs  $(Y, S)$   
 717 and  $(Y', S')$  on an edge  $uv$  such that the ancestor-descendant relationship is given, say  $y$  of  
 718  $Y$  has to be in the path from the root to  $y'$  of  $Y'$ , then we can do these plug ins in any order  
 719 but with some care. It is the same if we first plug in  $(Y, S)$  in the edge  $uv$  and then plug in  
 720  $(Y', S')$  in the edge  $yv$  or if we first plug in  $(Y', S')$  in the edge  $uv$  and then plug in  $(Y, S)$  in  
 721 the edge  $uy'$ . See Figure 5 for the an example.

**Figure 5** An example of plugging in two pairs  $(Y, \text{left})$  and  $(Y', \text{right})$  in a left edge  $uv$ .

722 For a subset of labels  $A \subseteq [k]$ , we define the feature template  $f_A$  by setting  $e(f_A) = 1$  if  
 723 and only if  $\text{lab}(e) \in A$  and  $e(f_A) = 0$  otherwise. With a small abuse of notation, we often  
 724 identify the feature template  $f_A$  with the corresponding subset of labels  $A$ .

725 Suppose we have a DT such that some feature label  $i$  occurs twice on a path from the  
 726 root to the leaves, say  $f_1$  is the instance closer to the root and  $f_2$  is the other instance. If  $f_2$   
 727 is in the left (resp. right) subtree of  $f_1$ , we remove  $f_2$ 's right (resp. left) subtree. In this case  
 728 we say we have done an *actual removal*.

729 Suppose we have a feature template labelled  $A$  in our DT. Let  $A_1, \dots, A_\ell$  be the sequence  
 730 of feature templates on the path from the root to  $A$  in order (not including  $A$ ). Let  $A'_i = A_i$

731 if  $A$  is in the right sub-tree of  $A_i$  and let  $A'_i = \overline{A_i}$  otherwise. If  $\overline{A} \subseteq A'_1 \cup \dots \cup A'_\ell$ , then we  
 732 remove the subtree rooted at the left child of  $A$ . If  $A \subseteq \overline{A'_1} \cup \dots \cup \overline{A'_\ell}$ , then we remove the  
 733 subtree rooted at the right child of  $A$ . In this case we say we have done a *template removal*.  
 734 If this procedure has been applied to a record exhaustively, we say that the DT is *reduced*.

735 To be short, for a DT  $T$  and a node  $v$ , we write  $v \in T$  instead of  $v \in V(T)$  and  $v \notin T$   
 736 otherwise. In a DT  $T$  we say that path  $p$  is a *downward* path if it is contained in a  
 737 path having the root as endpoint.

738 We now formally define two important operations. Given a DT  $T$ , we say that we *reduce*  
 739  $T$  if we exhaustively do actual removals and template removals. Call  $r(T)$  the resulting DT.

740 Recall that in any DT  $T$ , every non-leaf node  $v$  has one of the following three contents:  $v$   
 741 is a real feature (without label), or  $v$  is a feature with a label, or  $v$  is a future feature with  
 742 the corresponding subset of labels. A *relabelling*  $p$  for  $T$  is an assignment of contents of  $T$   
 743 as follows. Every feature is assigned to a feature with is either future, real or with a label.  
 744 We say that we *relabel* the DT  $T$  via the relabelling  $p$  if for every node of  $T$  we apply the  
 745 corresponding assignment and call  $p(T)$  the resulting DT.

746 The following lemma shows that, after repeatedly applying it the necessary amount of  
 747 times, to obtain a reduced DT after a sequence of relabels, it is safe to reduce at the end.

748 ▶ **Lemma 20** (Relabelling Lemma). *Let  $T$  be a DT and  $p$  be relabelling of  $T$ . Then  $(r \circ p \circ r)(T) = (r \circ p)(T)$ .*

750 **Proof.** For every  $v \in T$ , we want to prove  $v \in (r \circ p \circ r)(T) \Leftrightarrow v \in (r \circ p)(T)$ .

751  $\Rightarrow$  Suppose there is a node  $v \notin (r \circ p)(T)$ . Since  $v \in p(T)$ , there is a set of ancestors of  $v$   
 752 in  $p(T)$  that allows to remove  $v$ . Let  $A_v$  be the union of all the minimal set of ancestors of  $v$   
 753 in  $p(T)$  that allows to remove  $v$ . If  $A_v$  is a set of ancestors of  $v$  in  $T$  that allows to reduce  $v$   
 754 then  $v \notin r(T)$  and so  $v \notin (r \circ p \circ r)(T)$ . Otherwise let  $A'_v$  be the subset of  $A_v$  in  $(p \circ r)(T)$ .  
 755 We conclude by noting that  $A'_v$  contains one of the minimal sets  $A_v$  is composed of and so  
 756  $v \notin (r \circ p \circ r)(T)$ .

757  $\Leftarrow$  Suppose there is a node  $v \notin (r \circ p \circ r)(T)$ . If  $v \in (p \circ r)(T)$ , there exists a set  $A_v$  of  
 758 ancestors of  $v$  in  $(p \circ r)(T)$  that allows to reduce  $v$ . Then  $A_v$  is a set of ancestors of  $v$  in  $p(T)$   
 759 that allows to reduce  $v$  and so  $v \notin (r \circ p)(T)$ . If  $v \notin (p \circ r)(T)$  then  $v \notin r(T)$ : there exists a  
 760 set  $A_v$  of ancestors of  $v$  in  $T$  that allows to remove  $v$ . This means  $A_v$  is a set of ancestors of  
 761  $v$  in  $p(T)$  that allows to remove  $v$  and so  $v \notin (r \circ p)(T)$ . ◀

762 We say that a DT  $T$  is a *real DT* if every non-leaf node is either a real feature or a future  
 763 feature, whereas it is a *DT template* if it contains no real feature.

764 Let  $B$  be a rooted subcubic tree that corresponds to a  $k$ -NLC expression of the graph  
 765  $G_I(E)$ . For  $b \in V(B)$ , we write *feat*( $b$ ) and *exam*( $b$ ) for the sets of features and examples  
 766 introduced at node  $b$ . We say that a real DT  $T$  is a DT for the node  $b$  if every real feature of  
 767  $T$  is an element of *feat*( $b$ ) and every example in *exam*( $b$ ) is correctly classified by  $T$ , i.e. if  
 768  $e \in \text{exam}(b) \cap E^+$  then  $e$  ends in a leaf with a + label and if  $e \in \text{exam}(b) \cap E^-$  then  $e$  ends  
 769 in a leaf with a - label.

770 Given a real DT  $T$  and a node  $b \in B$ , often we want to perform a very specific composition  
 771 of operations. Let  $p_b$  be the following relabelling of  $T$ : every real feature of  $T$  is assigned to  
 772 a feature with the label given by the  $k$ -NLC expression at node  $b$  and every other feature is  
 773 assigned to itself. Then the composition  $r \circ p_b$  is called the *standard reduction* of  $T$  at node  
 774  $b$ . Given a DT  $T$  and a node  $b \in B$ , it is useful to give the following relabelling  $p'_b$ : every  
 775 feature with a label is assigned to the real feature of that node. The relabelling  $p'_b$  is called  
 776 the *real relabelling* of  $T$  at node  $b$ .

777 We say that a DT template  $T$  is a DT for the node  $b$  if there exists a real DT  $T'$  for  $b$  such  
778 that  $T$  is the standard reduction of  $T'$ . In this case we say that  $T'$  is the witness of  $T$  for  $b$ .

779 ▶ **Lemma 21.** *If there are  $\ell$  features with labels and  $2^h$  future features, then every reduced  
780 DT template has height at most  $\ell + h$ . Furthermore, every path from the root to the leaves  
781 contains at most  $\ell$  features with label and at most  $h - 1$  future features.*

782 **Proof.** Consider a path  $P$  of maximum length from the root to the leaves in a reduced DT  
783 template  $T$ . By the assumptions on  $T$ , no feature with label appears more than once on  
784 this path: the number of these feature nodes on this path is at most  $\ell$ . Consider two future  
785 features  $f_A$  and  $f_{A'}$  that appear in  $P$ , say  $f_A$  is the instance closer to the root. Since  $T$  is  
786 reduced, we must have that  $\emptyset \subset A' \subset A$ . Since the label of any future feature has at most  $h$   
787 elements, there can be at most  $h - 1$  feature template nodes on this path. The path ends  
788 with a leaf node, so this gives a total of  $\ell + h - 1 + 1 = \ell + h$  nodes, as required. ◀

789 ▶ **Lemma 22.** *If there are  $\ell$  features with label and  $2^h$  future features, then there are at  
790 most  $(\ell + 2^k + 2)2^{\ell+k+1}$  reduced DT templates. Furthermore, these can be enumerated in  
791  $\mathcal{O}((\ell + 2^k + 2)2^{\ell+k+1})$ -time.*

792 **Proof.** By Lemma 21, the tree has height at most  $\ell + k$ . Each node of the DT could be a  
793 feature with label, a future feature, or a leaf: at most  $\ell + 2^h + 2$  different contents. Since  
794 there are at most  $2^{\ell+h+1}$  nodes in the tree, there are at most  $(\ell + 2^h + 2)2^{\ell+h+1}$  possible  
795 DTs. ◀

796 The *semantics* for a record are defined as follows. We say that a pair  $(T, s)$  is a *record* for  
797 the node  $b \in B$  and we write  $(T, s) \in \mathcal{R}(b)$ , if  $T$  is a DT template for  $b$  and  $s$  is the minimum  
798 number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ .

### 799 3.5 Proof to the Main Result

800 Now, it suffices to compute  $\mathcal{R}(b)$  via leaf-to-root dynamic programming. The following  
801 four lemmas show how this can be achieved for all of the four types of nodes in a  $k$ -NLC  
802 expression tree  $B$ .

803 ▶ **Lemma 23 (leaf node).** *Let  $b \in V(B)$  be a leaf node. Then  $\mathcal{R}(b)$  can be computed in time  
804  $\mathcal{O}(k(2^k + 3)2^{k+2})$ .*

805 **Proof.** Let  $v$  be the vertex of  $G_I(E)$  that corresponds to the leaf node  $b$ . This means either  
806  $v \in E$  or  $v \in \text{feat}(E)$ .

807 We have to enumerate all possible reduced DT templates  $T$  for  $b$ . It is enough to consider  
808 all reduced DT templates  $T$  of height at most  $k + 1$  and discard those that are not DT  
809 templates for  $b$ ; these can be enumerated in time  $\mathcal{O}((2^k + 3)2^{k+2})$  by Lemma 22 and the  
810 check can be done in time  $\mathcal{O}(k)$ . We add the pair  $(T, 0)$  to the set of records  $\mathcal{R}(b)$ .

811 Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if  
812 and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$   
813 of  $T$  for  $b$ .

814 We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction, we have that  
815  $s = 0$  and  $T$  is a DT template for  $b$  which is already reduced. Then  $T$  is trivially a witness  
816 of  $T$  for  $b$ .

817 Now we prove the backward direction. Let  $T$  be a reduced DT template such that  $0$   
818 is the minimum number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ .  
819 This means  $T'$  is obtained from  $T$  after the real relabelling at node  $b$  is applied:  $T$  is a DT  
820 template among the considered DTs above which leads to the fact that  $(T, 0) \in \mathcal{R}(b)$ . ◀

821 ▶ **Lemma 24** (join node). Let  $b \in V(B)$  be a join node. Then  $\mathcal{R}(b)$  can be computed in time  
 822  $\mathcal{O}(k(2k + 2^k + 2)2^{6k+1})$ .

823 **Proof.** Let  $b_L$  and  $b_R$  be the left, resp. right, child of  $b$  in  $B$ : we may assume the labels for  
 824  $feat(b_L)$  are in  $[k]$  and the labels for  $feat(b_R)$  are in  $[k']$ . Moreover, let  $M$  be the  $k \times k$   $\{0, 1\}$   
 825 matrix that represent the node  $b$ . Finally, for every label  $i \in [k]$ , let  $A_i = \{j \in [k] \mid M_{i,j} = 1\}$ .

826 We consider every reduced DT  $T$  for  $b$  with feature labels in  $[k] \cup [k']$  and future feature  
 827 labels in  $\mathcal{P}([k])$ ; these can be enumerated in time  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$  by Lemma 22.

828 For every such DT  $T$ , we create a DT  $T_L$  as follows. Let  $p_*$  be the following relabelling:  
 829 for every  $i' \in [k']$ , every feature with label  $i'$  is assigned to the future feature  $A_i$ . Then we  
 830 apply the composition  $r \circ p_*$  to  $T$ . In a symmetrical way we create a DT  $T_R$ . Let  $p'_*$  be the  
 831 following relabelling: for every  $i \in [k]$ , every feature with label  $i$  is assigned to the future  
 832 feature  $A_{i'}$  and every future feature  $A_i$  is assigned to the future feature  $A_{i'}$ . Then we apply  
 833 the composition  $r \circ p'_*$  to  $T$ .

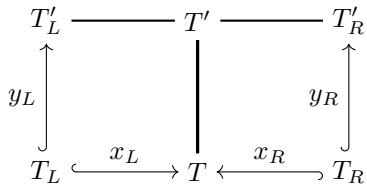

834 Now we want to understand if there is a record in  $\mathcal{R}(b_L)$  of the form  $(T_L, s_L)$  for some  
 835 positive integer  $s_L$  and if there is a record in  $\mathcal{R}(b_R)$  of the form  $(T_R, s_R)$  for some positive  
 836 integer  $s_R$ : if the answer is yes in both cases, we add a record  $(T, s_L + s_R)$  to  $\mathcal{R}(b)$ ; otherwise  
 837 we discard this option.

838 Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Every reduced DT  $T$  can  
 839 be enumerated in time  $\mathcal{O}((2k + 2^k + 2)2^{3k+1})$  by Lemma 22. For every such DT  $T$ , there are  
 840 at most  $2^{3k}$  paths from the root to the leaves and for every of these paths there are at most  
 841  $k$  nodes for each of the following: features with label in  $[k]$ , features with label in  $[k']$  and  
 842 future features by Lemma 21. This means  $r \circ p_*$  and  $r \circ p'_*$  can be done in  $\mathcal{O}(k2^{3k})$  time.

843 Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ . We start with the  
 844 forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exist records  $(T_L, s_L) \in \mathcal{R}(b_L)$   
 845 and  $(T_R, s_R) \in \mathcal{R}(b_R)$  such that  $T_L$  and  $T_R$  are obtained by the application of  $r \circ p_*$  and  
 846  $r \circ p'_*$  respectively to  $T$  and  $s_L + s_R = s$ .

847 By induction, for  $H \in \{L, R\}$ , we know that  $s_H$  is the minimum number of elements that  
 848 have been deleted from a witness  $T'_H$  of  $T_H$  for  $b_H$ .

849 For  $H \in \{L, R\}$ , we define maps  $x_H$  and  $y_H$  as follows. Let  $x_H : V(T_H) \rightarrow V(T)$  and  
 850  $y_H : V(T_H) \rightarrow V(T'_H)$  be the functions that maps every node of  $T_H$  to the corresponding  
 851 node in  $T$  and in  $T'_H$  and note that by constructions both these maps are injective.

852 Moreover,  $V(T) \setminus Im(x_H)$  and  $V(T'_H) \setminus Im(y_H)$  can be partitioned into subtrees that  
 853 have been deleted after the application of  $r \circ p_*$ ,  $r \circ p'_*$  on  $T$  or of the standard reduction  
 854 on  $T'_H$ : let  $X_H^*$  and  $Y_H^*$  be the set of roots of the above subtrees in  $V(T) \setminus Im(x_H)$  and  
 855  $V(T'_H) \setminus Im(y_H)$  respectively. In addition, for every element  $y \in Y_H^*$ , let  $Y_y^H$  be the maximal  
 856 subtree of  $T'_H$  rooted at  $y$  with no elements from  $Im(y_H)$  and that does not contain any  
 857 vertex from  $Y_H^* \setminus \{y\}$ ; let  $(Y_y^H, S_y^H)$  the corresponding single pair. In a similar way, for every  
 858 element  $x \in X_H^*$ , let  $X_x^H$  be the maximal subtree of  $T$  rooted at  $x$  with no elements from  
 859  $Im(x_H)$  and that does not contain any vertex from  $X_H^* \setminus \{x\}$ ; let  $(X_x^H, S_x^H)$  the corresponding

single pair. Finally, for every  $y \in Y_H^*$ , let  $P_y^H$  be the shortest downwards path in  $T'_H$  that contains  $y$  and with both endpoints in  $Im(y_H)$ , say  $y_H(t)$  and  $y_H(t')$ .

*Claim 1: For every  $H \in \{L, R\}$  and for every  $y, y' \in Y_H^*$ , the paths  $P_y^H$  and  $P_{y'}^H$  are either edge disjoint or  $P_y^H = P_{y'}^H$ .*

*Proof.* If  $P_y^H$  and  $P_{y'}^H$  are edge disjoint, then the statement is proven immediately. Suppose  $P_y^H$  and  $P_{y'}^H$  share an edge. By minimality and the fact they are downwards paths,  $P_y^H$  and  $P_{y'}^H$  share the endpoint towards the root. If they also share the other endpoint, then the statement is proven immediately. Suppose now their endpoints towards the leaves is different, say  $w$  and  $w'$ , and consider the last edge those paths have in common in a root-to-leaf order, say  $uv$ .

Without loss of generality, we can assume  $w$  belongs to the left branch of  $v$  and  $w'$  belongs to the right branch of  $v$ . Note that  $v \in V(T'_H) \setminus Im(y_H)$ , or we get a contradiction due the minimality of  $P_y^H$ . Now we get the following contradiction: by construction,  $w$  and  $w'$  are both elements of  $Im(y_H)$  but at least one of them must be in  $V(T'_H) \setminus Im(y_H)$  since it is an element of either  $Y_y^H$  or of  $Y_{y'}^H$ . This proves Claim 1.

Now for every  $y \in Y_H^*$  we consider the path  $Q_y^H$  in  $T$  having endpoints  $x_H(t)$  and  $x_H(t')$ .

Now we are able to describe how to obtain a witness  $T'$  of  $T$  for  $b$ . For every  $y \in Y_L^*$ , in the last edge of path  $Q_y^L$  we plug in the single pair  $(Y_{y'}^L, S_{y'}^L)$  rooted at  $y'$ , for every internal node  $y'$  of  $P_y^L$ , in the order the nodes  $y'$  appear in  $P_y^L$ . Note that, in the case an element of  $Y_L^*$  is present in more than one  $P_y^L$ , we plug in the corresponding single pair only once. Note also that whenever we plug in some single pair  $(Y_y^L, S_y^L)$  in a DT, the tree  $Y_y^L$  has real features and future features as nodes. Call this graph  $T^*$ . Now we do the same sequence of plug ins of the single pairs corresponding to the internal vertices of  $P_y^R$  in the last edge of the path  $Q_y^R$ . Again, in the case an element of  $Y_R^*$  is present in more than one  $P_y^R$ , we plug in the corresponding single pair only once. Call the tree obtained in this way  $T'$ . Note that  $T'$  contains real features from  $feat(b_L)$  and from  $feat(b_R)$  and future features with labels in  $\mathcal{P}([k])$ .

To conclude this part of the proof we have to show two things: (i)  $T$  is obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a real DT for  $b$ . We start proving (i): by construction  $T'$  is obtained from  $T$  after adding  $s_L$  elements from  $T'_L$  and  $s_R$  elements from  $T'_R$ , and so with  $s_L + s_R = s$  more elements.

Before considering statement (ii), we consider the following relabelling  $p_+$  of  $T'$ : every real feature in  $feat(b_R)$  is assigned to a feature with its label at node  $b_R$  and every other feature is assigned to itself. The real DT  $T'_L$  can be obtained from  $T'$  by the application of the composition  $r \circ p_* \circ p_+$ .

Now we consider statement (ii). We show that given an example  $e \in exam(b_L)$ ,  $e$  is correctly classified by  $T'$  and to do so we show that  $e$  ends in a leaf of  $T'$  that corresponds to the leaf where  $e$  ends in  $T'_L$ . Say that  $e$  goes along a path  $P$  of  $T'_L$  from the root to a leaf  $\ell$  and let  $Q$  be the corresponding path in  $T'$ , i.e. the path from  $r$  to  $\ell$  (note that by construction  $\ell$  is present in  $T'$  and is still a leaf). Let  $v$  be a node of  $Q$ , we can have the following different cases.

- 901 ■  $v$  is a real feature from  $feat(b_L)$ :  $v$  is also present in  $T'_L$  as real feature;
- 902 ■  $v$  is a real feature from  $feat(b_R)$ :  $v$  might not be present in  $T'_L$  due reductions but if it is 903 present it is a future feature  $A_i$  for some  $i \in [k]$ ;
- 904 ■  $v$  is a future feature  $f_A$ :  $v$  might not be present in  $T'_L$  due reductions but if it is present 905 it is still the same future feature  $A_i$ .

906     If  $v$  is present in  $T'_L$  then the behaviour of  $v$  on  $e$  in  $T'_L$  and in  $T'$  is the same. Suppose  
 907     now  $v$  is a node of  $Q$  that is being reduced due his label and so it is not present in  $T'_L$ .  
 908     This means there is a set of ancestors of  $v$  such that their labels allows to remove  $v$  and by  
 909     construction  $v$  behaves on  $e$  like those ancestors. This proves  $e$  goes along  $Q$  and in particular  
 910     it ends at leaf  $\ell$  and so  $T'$  is a real DT for  $b_L$ . With symmetric construction, we show that  
 911      $T'$  is also a real DT for  $b_R$ .

912     Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum  
 913     number of elements that have been deleted from a witness  $T'$  of  $T$  for  $b$ . In particular, we  
 914     recall that  $T'$  is a real DT for  $b$  with actual feature labels in  $[k] \cup [k']$  and future feature  
 915     labels in  $\mathcal{P}([k])$ .

916     We create at real DT  $T'_L$  by the application of the composition  $r \circ p_* \circ p_+$  to  $T'$ . By  
 917     assumption  $T'$  is a real DT for  $b_L$  and by construction  $T'_L$  is a real DT for  $b_L$ . Denote  
 918     with  $T_L$  the DT template obtained from  $T'_L$  by standard reduction and denote with  $s_L$   
 919     the number of nodes that have been deleted from  $T'_L$  to obtain  $T$ . By induction we have  
 920      $(T_L, s_L) \in \mathcal{R}(b_L)$ . Now we note that  $T_L$  is obtained from  $T$  after the application of the  
 921     composition  $r \circ p_*$ . In a symmetric way, we construct  $T'_R$ ,  $T_R$  and the record  $(T_R, s_R) \in \mathcal{R}(b_R)$ .  
 922     Then  $(T, s_L + s_R) \in \mathcal{R}(b)$ .  $\blacktriangleleft$

923     ► **Lemma 25** (relabel node). *Let  $b \in V(B)$  be relabel node. Then  $\mathcal{R}(b)$  can be computed in  
 924     time  $\mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$ .*

925     **Proof.** Let  $b_C$  be the unique child of  $b$  in  $B$ . Let  $R$  be the mapping of  $[k]$  to itself that  
 926     represent the node  $b$ . Moreover, since we are considering a *nice* NLC-expression we can  
 927     assume  $R$  is the identity mapping, i.e.  $R(\ell) = \ell$ , for all values except for a unique element  $i$   
 928     of its domain, i.e.  $R(i) = j$  for some  $j \in [k] \setminus \{i\}$ .

929     We say that a future feature  $A$  is *good* if it does not distinguish between  $i$  and  $j$ , that  
 930     is  $i \in A$  if and only if  $j \in A$ , and *bad* otherwise. Let  $(T_C, s_C)$  be an element of  $\mathcal{R}(b_C)$ . Let  
 931      $p''$  the following relabelling of the DT template  $T_C$ : every feature with label  $i$  is assigned  
 932     to label  $j$  and every future feature with label  $A$  is assigned to the future feature with label  
 933      $A \setminus \{i\}$ .

934     If  $T_C$  has a bad future feature then we do not take any other action. Suppose now  $T_C$   
 935     has only good future features; now let  $T$  be the DT template obtained from  $T_C$  after the  
 936     application of the composition  $r \circ p''$  and let  $s^*$  be the number of nodes that have been  
 937     deleted from  $T_C$  to  $T$ .

938     If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  $s' \leq s_C + s^*$  then we do  
 939     not take any other action. If there is a record in  $\mathcal{R}(b)$  of the form  $(T, s')$  for some integer  
 940      $s' > s_C + s^*$  then we replace it with  $(T, s_C + s^*)$ . If there is no record in  $\mathcal{R}(b)$  of the form  
 941      $(T, s')$  for some integer  $s'$  then we add  $(T, s_C + s^*)$  to  $\mathcal{R}(b)$ .

942     Now we want to evaluate the running time of computing  $\mathcal{R}(b)$ . Consider record  $(T_C, s_C)$   
 943     in  $\mathcal{R}(b_C)$ . In  $\mathcal{O}(k)$  time we check if  $T_C$  all the future features are good. For every such DT  
 944      $T_C$ , there are at most  $2^{2k}$  paths from the root to the leaves and for every of these paths there  
 945     are at most  $k$  nodes for each of the following: feature with label  $i$  and and future feature  
 946     that contains  $i$ . This means  $r \circ p''$  can be done in  $\mathcal{O}(k)$  time. This means to compute  $\mathcal{R}(b)$   
 947     takes  $\mathcal{O}(k|\mathcal{R}(b_C)|) = \mathcal{O}(k(2k + 2^k + 2)2^{3k+1})$  time.

948     Now we have to show the correctness of the construction for  $\mathcal{R}(b)$ , i.e.  $(T, s) \in \mathcal{R}(b)$  if  
 949     and only if  $s$  is the minimum number of elements that have been deleted from a witness  $T'$   
 950     of  $T$  for  $b$ .

951 We start with the forward direction. Let  $(T, s) \in \mathcal{R}(b)$ . By construction there exists a  
 952 record  $(T_C, s_C) \in \mathcal{R}(b_C)$  such that  $T$  is obtained from  $T_C$  after the application of  $r \circ p''$  and  
 953 let  $s^* = s - s_C$ . By induction  $s_C$  is the minimum amount of nodes that have been deleted  
 954 from a witness  $T'_C$  of  $T_C$  for  $b_C$ . By construction we also know that every future feature of  
 955 both  $T'_C$  and  $T_C$  is good.

956 Denote with  $T'$  the real DT obtained  $T'_C$  after the application of  $r \circ p''$ : note that this  
 957 last reduction does not any node since every future feature of  $T'_C$  is good and there is no  
 958 feature with label  $i$ . To conclude this part of the proof we have to show two things: (i)  $T$  is  
 959 obtained from  $T'$  after removing  $s$  vertices; (ii)  $T'$  is a witness of  $T$  for  $b$ .

960 Before proving (i), we describe how  $T$  can be obtained from  $T'$ . Let  $p'''$  be the following  
 961 relabelling of  $T'$ : every real feature that contains  $j$  is assigned to the real feature  $A \cup \{i\}$   
 962 and every other feature is assigned to itself. Then the application of the composition  $p'''$ ,  
 963 the standard reduction and  $r \circ p''$  to  $T'$  is exactly the standard reduction for  $T'$  which then  
 964 result to the DT template  $T$ . By Lemma 20 the score of the standard reduction from  $T'$  to  
 965  $T$  is exactly  $s_C + s^* = s$ .

966 Now we consider statement (ii). First note that  $\text{exam}(b) = \text{exam}(b_C)$ . We show that  
 967 a given example  $e \in \text{exam}(b)$  is correctly classified by  $T'$ . Say that  $e$  goes along a path  $P$   
 968 of  $T'_C$  from the root to a leaf  $\ell$ . We show  $e$  goes along the path  $P$  in  $T'$  as well: every real  
 969 feature has not changed and so  $e$  behaves the same. Since every future feature of  $T'_C$  is good,  
 970 then  $e$  behave the same on the corresponding future feature of  $T'$ .

971 Now we prove the backward direction. Let  $T$  be a reduced DT such that  $s$  is the minimum  
 972 number of elements that have been deleted from a witness  $T'$  of  $B$  for  $b$ . In particular, we  
 973 recall that real  $T'$  is a DT for  $b$  with real features and future feature labels in  $\mathcal{P}([k] \setminus \{i\})$ .

974 We create the real DT  $T'_C$  as the application of  $r \circ p'''$  to  $T'$ , the DT template  $T_C$  as the  
 975 application of the standard reduction to  $T'_C$ . By construction we have  $(T_C, s_C) \in \mathcal{R}(b_C)$ ,  
 976 where  $s_C$  is the number of nodes that have been removed from  $T'_C$  to  $T_C$ . Note that  $T_C$  has  
 977 only good future features. Finally we note that  $T$  is obtained from  $T_C$  by the application of  
 978  $r \circ p''$ .  $\blacktriangleleft$

979 Now we can finally prove Theorem 4 and Theorem ??, which we restate here.

980 **Theorem 4 (restated).** *Let  $E$  be a CI, let  $(B, \chi)$  be an NLC-expression decomposition of  
 981 width  $k$  for  $G_I(E)$ , and let  $s$  be an integer. Then, deciding whether  $E$  has a DT of size at  
 982 most  $s$  is fixed-parameter tractable parameterized by  $k$ . In particular, such computation takes  
 983  $\mathcal{O}()$  time.*

984 **Proof.** We start off by computing  $\mathcal{R}(b)$  for every node  $b$  of  $B$ , via leaf-to-root dynamic  
 985 programming. An upper bound for the running time for this step is the number of nodes of  
 986  $B$  times the maximum running time to compute the record at each node which is given by  
 987 Lemmas 23, 24 and 25.

988 Now we look at the root node  $r$  of  $B$ . We go through all the records of  $\mathcal{R}(r)$  and select a  
 989 record  $(T, s) \in \mathcal{R}(r)$  such that  $|T| + s$  is minimum over all DTs with no future feature.  $\blacktriangleleft$

990 **Theorem ?? (restated).** *DTS is fixed-parameter tractable parameterized by NLC-width.*

## 991 4 An FPT-Algorithm for bounded solution size and $\delta_{max}$ .

992 In the following, let  $E$  be a CI and  $q \notin \text{feat}(E)$ . A *decision tree pattern*, or simply a *DT*  
 993 *pattern*,  $T$  is a rooted subcubic tree, where every leaf node is either a *positive* or *negative* leaf  
 994 and every non-leaf node is labelled with a feature in  $\text{feat}(E) \cup \{q\}$ . For every node  $v$  of a

995 DT pattern  $T$ , we indicate with  $feat_T(v)$  the label associated to that node. Finally we say  
 996 that an inner node  $v \in V(T)$  is a *fixed node* if  $feat_T(v) \in feat(E)$  and *non-fixed* otherwise.

997 A DT pattern  $T'$  is an *improvement* for a DT pattern  $T$  if  $T' = T$  as rooted trees and  
 998  $feat_{T'}(v) = feat_T(v)$  for every fixed node  $v$  of  $T$ . A *complete improvement*  $T'$  of  $T$  is an  
 999 improvement such that  $feat(T') \subseteq feat(E)$ . A *threshold assignment* for a DT pattern  $T$  is a  
 1000 function  $th$  that maps every fixed node  $v \in V(T)$  to a natural number  $th(v)$ . Note that any  
 1001 complete improvement  $T'$  of a DT pattern  $T$  can be made to a decision tree with a threshold  
 1002 assignment.

1003 Let  $T$  be a DT pattern and  $th$  be a threshold assignment for  $T$ , for each node  $v$  of  $T$  we  
 1004 define the set of examples that arrive at node  $v$ ,  $E_T(v)$  as follows:  $E_T(v)$  is the set of all  
 1005 examples  $e \in E$  such that for each left (right, respectively) arc  $(u, w)$  on the unique path from  
 1006 the root of  $T$  to  $v$  either  $u$  is a fixed node and  $(feat(u))(e) \leq th(u)$  ( $(feat(u))(e) > th(u)$ ,  
 1007 respectively) or  $u$  is a non-fixed node. A DT pattern  $T$  is *valid* for a set of examples  $E' \subseteq E$   
 1008 if there is threshold assignment for the fixed nodes such that for every positive (negative)  
 1009 example  $e$ ,  $e \in E_T(v)$  for a positive (negative) leaf  $v$ .

1010 The definition of  $E_T(v)$  is an indication of the behaviour of feature  $q$  and of non-fixed  
 1011 nodes. Informally, if any example reaches at a non-fixed node of  $T$  then it reaches both his  
 1012 children. While no feature in  $feat(E)$  can simulate such behaviour for any threshold,  $q$   
 1013 simultaneously cover the two cases a feature with his threshold does not distinguish any two  
 1014 examples.

## 1015 4.1 Preprocess

1016 Let  $E$  be a CI and  $T$  be a DT pattern. For every  $v \in V(T)$ , we define the set of *expected*  
 1017 *examples*  $E_v$  as follows:

- 1018   ■ if  $v$  is the root, then  $E_v = E$ ;
- 1019   ■ if  $v$  is the left child of a fixed node  $v_p$ , then  $E_v = E_{v_p}[feat(v_p) \leq th_L(v_p) + 1]$ ;
- 1020   ■ if  $v$  is the right child of a fixed node  $v_p$ , then  $E_v = E_{v_p}[feat(v_p) > th_R(v_p) - 1]$ ;
- 1021   ■ if  $v$  is a child of a non-fixed node  $v_p$ , then  $E_v = E_{v_p}$ .

1022 Node that the definition of  $E_v$  is strictly related with the following: if  $v$  is a fixed node,  
 1023 let  $c_\ell$  and  $c_r$  be the left, resp. right, child of  $v$ , we define two values  $th_L(v)$  and  $th_R(v)$  as  
 1024 follows:

- 1025   ■ let  $th_L(v)$  be the maximum value in  $D_E(feat(v))$  such that  $T_{c_\ell}$  is valid for  $E_v[feat(v) \leq$   
 1026       $th_L(v)]$ ;
- 1027   ■ let  $th_R(v)$  be the minimum value in  $D_E(feat(v))$  such that  $T_{c_r}$  is valid for  $E_v[feat(v) >$   
 1028       $th_R(v)]$ .

1029 Before formally proving in Lemma 28 that we are able to compute  $E_v$  and  $th_L(v)$ ,  $th_R(v)$   
 1030 (when  $v$  is a fixed node) for every  $v \in V(T)$ , we want to describe the role of  $E_v$  in the proof  
 1031 of Lemma 30.

1032 Let us consider the following situation. Suppose we are trying to find a DT of minimum  
 1033 size for a CI  $E$  using at least the features in a given support set  $S$ . The first step would be  
 1034 to compute a minimum size DT  $T^*$  for  $E$  such that  $feat(T^*) = S$ . Next we analyse the case  
 1035 an optimal DT for  $E$  uses not only every feature from  $S$  but some additional feature: for  
 1036 this reason we consider DT patterns  $T$  of size at most  $s$  and such that  $feat(T) = S \cup \{q\}$ .

1037 Let  $E$  be a CI,  $S$  be a support set for  $E$  and  $T$  be a DT pattern of size at most  $s$  such  
 1038 that  $feat(T) = S \cup \{q\}$ . If  $T$  is a valid DT pattern for  $E$ , then  $T$ , and every  $T'$  obtained  
 1039 after left/right-contracting every non-fixed node  $v$  of  $T$ , can be easily extended to a solution.

1040 The following two lemmas cover the case  $T$  is not a valid DT pattern for  $E$ .

1041 ▶ **Lemma 26.** *Let  $T$  be a DT pattern that is not valid for  $E$ . For every node  $v$  of  $T$  it holds  
1042 that  $T_v$  is not valid for  $E_v$ .*

1043 **Proof.** Let  $T$  be a DT pattern that is not valid for  $E$ . We show this statement in a root-to-leaves fashion: first we show the statement holds for the root; then we prove it holds for every other node, given the fact it holds for each of its ancestors (or its parent). Let  $r$  be the root of  $T$ . By definition  $E_r = E$  and  $T_r = T$  and so the statement follows directly from the assumption.

1048 Let  $v$  be the left child of a fixed node  $v_p$ . By the definition of  $th_L(v_p)$ , the DT pattern  
1049  $T_v$  is not valid for  $E_v = E_{v_p}[feat(v_p) \leq th_L(v_p) + 1]$ . Similarly if  $v$  is the right child of a  
1050 fixed node  $v_p$ , the DT pattern  $T_v$  is not valid for  $E_v = E_{v_p}[feat(v_p) > th_R(v_p) - 1]$ .

1051 Let  $v$  be a child of a non-fixed node  $v_p$ . Suppose by contradiction that  $T_v$  is valid for  
1052  $E_v$ . We show that  $T_{v_p}$  is valid for  $E_{v_p}$  and consequently reaching a contradiction with the  
1053 assumption: any threshold assignment for the fixed nodes of  $T_v$  that is a witness of the  
1054 validity of  $T_v$  for  $E_v$  is also threshold assignment for the fixed nodes of  $T_{v_p}$  that is a witness  
1055 of the validity of  $T_{v_p}$  for  $E_{v_p} = E_v$ ; note this is true because  $v_p$  is a non-fixed node. ◀

1056 ▶ **Lemma 27.** *Let  $T$  be a DT pattern that is not valid for  $E$ . For every fixed node  $v$  of  $T$  it  
1057 holds that  $th_L(v) < th_R(v)$ .*

1058 **Proof.** Let  $T$  be a DT pattern that is not valid for  $E$ . Suppose by contradiction that there  
1059 is a fixed node  $v^*$  such that  $th_L(v^*) \geq th_R(v^*)$ . Let  $c_\ell$  and  $c_r$  be the left and right child  
1060 of  $v^*$ . We can set the threshold for  $feat(v^*)$  as  $th_L(v^*)$  and note that, by definition and  
1061 the assumption,  $T_{c_\ell}$  is valid for  $E_{c_\ell}$  and  $T_{c_r}$  is valid for  $E_{c_r}$ . This is a contradiction with  
1062 Lemma 26 as for every node  $v \in V(T)$ ,  $T_v$  is not valid for  $E_v$ . ◀

1063 Now we are finally ready to prove we can efficiently compute  $E_v$ ,  $th_L(v)$  and  $th_R(v)$  for  
1064 every node  $v \in V(T)$ .

1065 ▶ **Lemma 28.** *Let  $E$  be a CI, let  $T$  be a DT pattern of depth at most  $d$ . Then there is an  
1066 algorithm that runs in time  $\mathcal{O}(2^{d^2/2}n^{1+o(1)} \log n)$  and computes the set  $E_v$  and thresholds  
1067  $th_L(v)$  and  $th_R(v)$  for every node  $v \in V(T)$ .*

1068 **Proof.** The idea is to use the recursive algorithm **findLR** illustrated in Algorithm 1. That  
1069 is, given  $E$ ,  $T$ , the algorithm **findLR** attempts to find the triple  $(E_v, th_L(v), th_R(v))$  for  
1070 every node  $v \in V(T)$ . Lines 3 to 4: if  $T$  consists of a leaf node, the algorithm just report  
1071  $(E, \text{nil}, \text{nil})$ . Let  $c_\ell$  and  $c_r$  be the left, resp. right, child of the root  $v$ . Lines 6 to 11: if the  
1072 root of  $T$  is a non-fixed node, the algorithm calls itself recursively to compute on  $(E, T_{c_\ell})$   
1073 and  $(E, T_{c_r})$ . Lines 13 to 15: if the root of  $T$  is a fixed node  $v$ , the algorithm computes the  
1074 pair  $(t_\ell, t_r)$  for the root using the algorithm **binarySearch** and then calls itself recursively  
1075 to compute the triple for  $(E[feat(v) \leq t_\ell + 1], T_{c_\ell})$  and  $(E[feat(v) > t_r - 1], T_{c_r})$ .

1076 A key element for the correctness of **findLR** is the algorithm **binarySearch** illustrated  
1077 in Algorithm 2. Given  $E$ ,  $T$ ,  $f$ ,  $c_\ell$  and  $c_r$ , this algorithm computes the pair  $(t_\ell, t_r)$  for the  
1078 root of  $T$  that has feature  $f$ . This sub-routine performs a standard binary search procedure  
1079 on the array  $D$  containing all the values in  $D_E(f)$  in ascending order to find maximum  $t_\ell$  and  
1080 minimum  $t_r$  such that  $T_{c_\ell}$  and  $T_{c_r}$  can be extended to DT for  $E[f \leq t_\ell]$  and for  $E[f > t_r]$   
1081 respectively. To achieve this, the sub-routine makes at most  $\log |E|$  calls to **findTH**; note  
1082 that each of those calls is made for a tree of smaller depth. Lines 3 to 12: the algorithm  
1083 finds the maximum  $t_\ell$  by calling algorithm **findTH** in Line 6 repeatedly. Lines 13 to 22: the  
1084 algorithm finds the minimum  $t_r$  by calling algorithm **findTH** in Line 16 repeatedly.

1085 A sub-routine used for **binarySearch** is the algorithm **findTH** illustrated in Algorithm 3.  
 1086 This algorithm is very similar to Algorithm 1 but the output is some way much simpler.

1087 The running time of Algorithm 1 can now be obtained by multiplying the number of  
 1088 recursive calls to **findLR** with the time required for one recursive call. To obtain the number  
 1089 of recursive calls first note that if **findLR** is called with DT pattern of depth  $d$ , then it makes  
 1090 at most  $(2 \log n) + 2$  recursive calls to **findLR** with a pattern of depth at most  $d - 1$ , where  
 1091  $n = |E|$ . Therefore the number  $T(n, d)$  of recursive calls for a pattern of depth  $d$  is given  
 1092 by the recursion relation  $T(n, d) = (2(\log n) + 2)T(n, d - 1)$  starting with  $T(n, 0) = 0$ . This  
 1093 implies that  $T(n, d) \in \mathcal{O}((\log n)^d)$ . Finally, the runtime for one recursive call is easily seen to  
 1094 be at most  $\mathcal{O}(n \log n)$ . Hence, the total runtime of the algorithm is at most  $\mathcal{O}((\log n)^d n \log n)$ ,  
 1095 which because (see also [9, Exercise 3.18]):

$$1096 (\log n)^d \leq 2^{d^2/2} 2^{\log \log d^2/2} = 2^{d^2/2} n^{o(1)}$$

1097 is at most  $\mathcal{O}(2^{d^2/2} n^{1+o(1)} \log n)$ . ◀

---

**Algorithm 1** Algorithm to compute the triple  $(E_v, th_L(v), th_R(v))$  for every node  $v \in V(T)$ .

---

**Input:** CI  $E$ , DT pattern  $T$

**Output:** a triple  $(E_v, th_L(v), th_R(v))$  for every node  $v \in V(T)$ .

```

1: function findLR( $E, T$ )
2:    $r \leftarrow$  “root of  $T$ ”
3:   if  $r$  is a leaf then
4:     return  $(E, \text{nil}, \text{nil})$ 
5:    $c_\ell, c_r \leftarrow$  “left child and right child of  $r$ ”
6:   if  $r$  is a non-fixed node then
7:      $\lambda_\ell \leftarrow \text{FINDLR}(E, T_{c_\ell})$ 
8:      $\lambda_r \leftarrow \text{FINDLR}(E, T_{c_r})$ 
9:     if  $\lambda_\ell \neq \text{nil}$  and  $\lambda_r \neq \text{nil}$  then
10:      return  $(E, \text{nil}, \text{nil}) \cup \lambda_\ell \cup \lambda_r$ 
11:    return nil
12:    $f \leftarrow \text{feat}(r)$ 
13:    $(t_\ell, t_r) \leftarrow \text{BINARYSEARCH}(E, T, f, c_\ell, c_r)$ 
14:    $\lambda_\ell \leftarrow \text{FINDLR}(E[f \leq t_\ell + 1], T_{c_\ell})$ 
15:    $\lambda_r \leftarrow \text{FINDLR}(E[f > t_r - 1], T_{c_r})$ 
16:   return  $(E, t_\ell, t_r) \cup \lambda_\ell \cup \lambda_r$ 

```

---

1098 **4.2 The algorithm**

1099 Now we have computed a set  $E_v$  for every node  $v \in V(T)$ , whether it is a leaf, fixed or  
 1100 non-fixed node. A *pool set* for node  $v \in V(T)$  is a set  $\Pi(v) \subseteq E_v$ , such that if  $\Pi(v) \subseteq E_T(v)$   
 1101 then either

- 1102   ■  $T_v$  is not valid for  $E_v$ , or
- 1103   ■ for any complete improvement  $T'_v$  for  $T_v$  that is valid for  $E_v$ , there are two elements  
 1104      $e, e' \in \Pi(v)$  and there is a non-fixed node  $u$  for  $T$  such that  $\text{feat}_{T'}(u)$  must distinguish  $e$   
 1105     and  $e'$ .

1106 For every node  $v \in V(T)$ , we define  $\Pi(v)$  in a leaves-to-root fashion as follows. If  $v$  is  
 1107 a negative leaf then  $\Pi(v) = \{e^+\}$ , where  $e^+$  is any example in  $E^+ \cap E_v$ ; similarly, if  $v$  is a

■ **Algorithm 2** Algorithm to compute the pair  $(th_L(r), th_R(r))$  for the root  $r$  of  $T$

---

**Input:** CI  $E$ , DT pattern  $T$ , feature  $f$  of the root of  $T$ , left child  $c_\ell$  of the root of  $T$ , right child  $c_r$  of the root of  $T$

**Output:** maximum threshold  $t_\ell$  in  $D_E(f)$  for  $f$  such that  $(T_{c_\ell}, \alpha)$  can classify every example in  $E[f \leq t_\ell]$  and minimum threshold  $t_r$  in  $D_E(f)$  for  $f$  such that  $(T_{c_r}, \alpha)$  can classify  $E[f > t_r]$

```

1: function binarySearch( $E, T, f, c_\ell, c_r$ )
2:    $D \leftarrow$  “array containing all elements in  $D_E(f)$  in
      ascending order”
3:    $L \leftarrow 0; R \leftarrow |D_E(f)| - 1; b \leftarrow 0$ 
4:   while  $L \leq R$  do
5:      $m \leftarrow \lfloor (L + R)/2 \rfloor$ 
6:     if FINDTH( $E[f \leq D[m]], T_{c_\ell}$ ) = TRUE then
7:        $L \leftarrow m + 1; b \leftarrow 1$ 
8:     else
9:        $R \leftarrow m - 1; b \leftarrow 0$ 
10:    if  $b = 1$  then
11:       $t_\ell \leftarrow D[m]$ 
12:     $t_\ell \leftarrow D[m - 1]$                                  $\triangleright$  assuming that  $D[-1] = D[0] - 1$ 
13:     $L \leftarrow 0; R \leftarrow |D_E(f)| - 1; b \leftarrow 0$ 
14:    while  $L \leq R$  do
15:       $m \leftarrow \lfloor (L + R)/2 \rfloor$ 
16:      if FINDTH( $E[f > D[m]], T_{c_r}$ ) = TRUE then
17:         $R \leftarrow m - 1; b \leftarrow 1$ 
18:      else
19:         $L \leftarrow m + 1; b \leftarrow 0$ 
20:    if  $b = 1$  then
21:       $t_r \leftarrow D[m]$ 
22:     $t_r \leftarrow D[m + 1]$                                  $\triangleright$  assuming that  $D[|D_E(f)|] = D[|D_E(f)| - 1] + 1$ 
23:  return  $(t_\ell, t_r)$ 

```

---

positive leaf then  $\Pi(v) = \{e^-\}$ , where  $e^-$  is any example in  $E^- \cap E_v$ . Let  $c_\ell$  and  $c_r$  be the left, resp. right, child of  $v$ , then  $\Pi(v) = \Pi(c_\ell) \cup \Pi(c_r)$ .

Now we want to show that the construction of  $\Pi$  is correct, that is:

► **Lemma 29.**  $\Pi(v)$  is a pool set for  $v$  for every node  $v \in V(T)$ .

**Proof.** We show this by induction on the depth of  $T$  and let  $v$  be the root of  $T$ . Since  $E_T(v) = E$  it is trivial to note that  $\Pi(v) \subseteq E_T(v)$ . We start proving the base case: let  $T$  be a pattern of depth 0. Suppose  $v$  is negative leaf. Since  $E_v = E$  is not uniform, there is an example  $e^+ \in E^+ \cap E_v$ . The case where  $v$  is a positive leaf can be proved in a symmetrical manner.

Now, let  $T$  be a pattern of depth at least one and let  $c_\ell$  and  $c_r$  be the left and right child of  $v$ . Suppose first that  $v$  is a fixed node and let  $f = \text{feat}(v)$ . Thanks to Lemma 26, for every  $e_\ell \in \Pi(c_\ell)$  and  $e_r \in \Pi(c_r)$ , we know that  $f(e_\ell) < f(e_r)$ . This means that either  $\Pi(c_\ell) \subseteq E_T(c_\ell)$  or  $\Pi(c_r) \subseteq E_T(c_r)$ , say that  $\Pi(c_i) \subseteq E_T(c_i)$ , for  $i \in \{\ell, r\}$ . Since  $T_{c_i}$  has depth smaller than  $T_v = T$ , by the inductive hypothesis  $\Pi(c_i)$  is a pool set for  $c_i$ .

Finally suppose  $v$  is a non-fixed node. Let us consider any complete improvement  $T'_v$  for  $T_v$ . For any threshold assignment for  $T'_v$ , we have one of the following three cases: either  $\Pi(c_\ell) \subseteq E_{T'}(c_\ell)$  or  $\Pi(c_r) \subseteq E_{T'}(c_r)$  or there is an example  $e_\ell \in \Pi(c_\ell)$  and an example  $e_r \in \Pi(c_r)$  such that  $e_\ell \in E_{T'}(c_r)$  and  $e_r \in E_{T'}(c_\ell)$ . In the first two cases the statement is again proven thanks to the inductive hypothesis since  $T_{c_\ell}$  and  $T_{c_r}$  have depth smaller than

### Algorithm 3

---

**Input:** CI  $E$ , pattern  $T$

**Output:** TRUE if  $T$  can classify all examples in  $E$ , FALSE otherwise

```

1: function findTH( $E, T$ )
2:    $r \leftarrow$  “root of  $T$ ”
3:   if  $r$  is a leaf then
4:     if  $E$  is not uniform then
5:       return FALSE
6:     return TRUE
7:    $c_\ell, c_r \leftarrow$  “left child and right child of  $r$ ”
8:   if  $r$  is a non-fixed then
9:      $\lambda_\ell \leftarrow \text{FINDTH}(E, T_{c_\ell})$ 
10:     $\lambda_r \leftarrow \text{FINDTH}(E, T_{c_r})$ 
11:    if  $\lambda_\ell = \text{TRUE}$  and  $\lambda_r = \text{TRUE}$  then
12:      return TRUE
13:    return FALSE
14:    $f \leftarrow \text{feat}(r)$ 
15:    $t \leftarrow \text{BINARYSEARCH}(E, T, f, c_\ell, c_r)$ 
16:    $\lambda_\ell \leftarrow \text{FINDLR}(E[f \leq t_\ell + 1], T_{c_\ell})$ 
17:    $\lambda_r \leftarrow \text{FINDLR}(E[f > t_r - 1], T_{c_r})$ 
18:   if  $\lambda_r = \text{FALSE}$  then
19:     return FALSE
20:   return TRUE

```

---

1127     $T_v$ . In the third case,  $v$  is a non-fixed node for  $T$  such that  $\text{feat}_{T'}(v)$  distinguishes  $e_\ell$  and  
1128     $e_r$ .  $\blacktriangleleft$

1129    In particular, let us consider the pool set  $\Pi(r)$  for the root  $r$  of  $T$ , we define  $\Pi(T) := \Pi(r)$ .  
1130    In this way given  $T$ , we are able to compute the corresponding pool set.

1131    Let  $S$  be a support set for a CI  $E$ , we stay that  $B \subseteq \text{feat}(E)$  is a *branching set* for  $S$  if  
1132    for every minimal DT  $T$  for  $E$  such that  $S \subset \text{feat}(T)$  then  $B \cap (\text{feat}(T) \setminus S) \neq \emptyset$ .

1133    ▶ **Lemma 30.** *There is a  $\mathcal{O}(2^{d^2/2} s^{2s+1} n^{1+o(1)} \log n)$  time algorithm that given a support set  
1134     $S$  computes a branching set  $R_0$  for  $S$  of size at most  $s^{2s+3} \delta_{\max}$ .*

1135    **Proof.** Let  $E$  be a CI, a support set  $S$  for  $E$  and an integer  $s$ . We start by enumerating all  
1136    DT patterns  $T$  of size at most  $s$  such that  $\text{feat}(T) = S \cup \{q\}$ . For every such DT pattern  
1137     $T$ , thanks to Lemma 28, we are able to obtain the set  $E_v$  for every node  $v \in V(T)$  in time  
1138     $\mathcal{O}(2^{d^2/2} n^{1+o(1)} \log n)$ . In a leaves-to-root fashion, we are able to compute the set  $\Pi(v)$  for  
1139    every node  $v \in V(T)$  and ultimately  $\Pi(T)$ .

1140    Let  $R(T)$  be the set of all the features in  $\text{feat}(E) \setminus S$  that distinguish at least two examples  
1141    in  $\Pi(T)$ . The algorithm returns the set of features  $R_0$  obtained by considering the union of  
1142    the sets  $R(T)$  over all these DT patterns  $T$  of size at most  $s$ . By Lemma 1 this algorithm  
1143    runs in time  $\mathcal{O}(2^{d^2/2} s^{2s+1} n^{1+o(1)} \log n)$ .

1144    Now we show the size of  $R_0$  is bounded. By construction  $|\Pi(T)| \leq |T| \leq s$ ; for every two  
1145    distinct elements of  $\Pi(T)$ , by definition, there are at most  $\delta_{\max}$  features that distinguish  
1146    such two examples. This means that  $|R(T)| \leq s^2 \delta_{\max}$  and so  $R_0$  has size at most  $s^{2s+3} \delta_{\max}$ .

1147    We are left to show that  $R_0$  is a branching set for  $S$ . Let  $T$  be a minimal DT for  $E$  such  
1148    that  $S \subset \text{feat}(T)$  and suppose by contradiction that  $R_0 \cap (\text{feat}(T) \setminus S) = \emptyset$ . In particular we  
1149    have that  $R(T) \cap (\text{feat}(T) \setminus S) = \emptyset$ . This means that for every feature  $f$  of  $T$  that does not  
1150    belong to  $S$ ,  $f$  does not distinguish any two elements in  $\Pi(T)$ . By Lemma 29,  $\Pi(T) = \Pi(r)$ ,  
1151    where  $r$  is the root of  $T$ , is a pool set and so  $T$  is not valid for  $E$ , which is a contradiction.  $\blacktriangleleft$

1152 ► **Lemma 31** ([23]). Let  $E$  be a CI and let  $k$  be an integer. Then there is an algorithm that  
 1153 in time  $\mathcal{O}(\delta_{\max}(E)^k |E|)$  enumerates all (of the at most  $\delta_{\max}(E)^k$ ) minimal support sets of  
 1154 size at most  $k$  for  $E$ .

1155 ► **Lemma 32** ([23]). Let  $T$  be a DT of minimum size for  $E$  and let  $S$  be a support set  
 1156 contained in  $\text{feat}(T)$ . Then, the set  $R = \text{feat}(T) \setminus S$  is useful.

1157 ► **Observation 33** ([23]). Let  $T$  be a DT for a CI  $E$ , then  $\text{feat}(T)$  is a support set of  $E$ .

1158 **Proof.** Suppose for a contradiction that this is not the case and there is an example  $e^+ \in E^+$   
 1159 and an example  $e^- \in E^-$  such that  $e^+$  and  $e^-$  agree on all features in  $\text{feat}(T)$ . Therefore,  
 1160  $e^+$  and  $e^-$  are contained in the same leaf node of  $T$ , contradicting our assumption that  $T$  is  
 1161 a DT. ◀

1162 ► **Theorem 34** ([23]). Let  $E$  be a CI,  $S \subseteq \text{feat}(E)$  be a support set for  $E$ , and let  $s$  and  
 1163  $d$  be integers. Then, there is an algorithm that runs in time  $2^{\mathcal{O}(s^2)} \|E\|^{1+o(1)} \log \|E\|$  and  
 1164 computes a DT of minimum size among all DTs  $T$  with  $\text{feat}(T) = S$  and  $\text{size}(T) \leq s$  if such  
 1165 a DT exists; otherwise **nil** is returned.

1166 ► **Theorem 35.** MINIMUM DECISION TREE SIZE is fixed-parameter tractable parametrized  
 1167 by  $\delta_{\max} + s$ .

1168 **Proof.** We start by presenting the algorithm for MINIMUM DECISION TREE SIZE, which is  
 1169 illustrated in Algorithm 4 and Algorithm 5.

1170 Given a CI  $E$  and an integer  $s$ , the algorithm returns a DT of minimum size among all  
 1171 DTs of size at most  $s$  if such a DT exists and otherwise the algorithm returns **nil**. The  
 1172 algorithm **minDT** starts by computing the set  $\mathcal{S}$  of all minimal support sets for  $E$  of size  
 1173 at most  $s$ , which because of Lemma 31 results in a set  $\mathcal{S}$  of size at most  $(\cdot)$ . In Line 4  
 1174 the algorithm then iterates over all sets  $S$  in  $\mathcal{S}$  and calls the function **minDTS** given in  
 1175 Algorithm 5 for  $E$ ,  $s$ , and  $S$ , which returns a DT of minimum size among all DTs  $T$  for  $E$   
 1176 of size at most  $s$  such that  $S \subseteq \text{feat}(T)$ . It then updates the currently best decision tree  $B$   
 1177 if necessary with the DT found by the function **minDTS**. Moreover, if the best DT found  
 1178 after going through all sets in  $\mathcal{S}$  has size at most  $s$ , it is returned (in Line 9), otherwise  
 1179 the algorithm returns **nil**. Finally, the function **minDTS** given in Algorithm 5 does the  
 1180 following. It first computes a DT  $T$  of minimum size that uses exactly the features in  $S$  using  
 1181 Lemma 34. It then tries to improve upon  $T$  with the help of useful sets. That is, it uses  
 1182 Lemma 30 to compute the branching set  $R_0$ . It then iterates over all (of the at most  $(\cdot)$ )  
 1183 features  $f \in R_0$  (using the for-loop in Line 4), and calls itself recursively on the support set  
 1184  $S \cup \{f\}$ . If this call finds a smaller DT, then the current best DT is updated. Finally, after  
 1185 the for-loop the algorithm either returns a solution if its size is less than  $s$  or **nil** otherwise.

1186 Towards showing the correctness of Algorithm 4, consider the case that  $E$  has a DT  
 1187 of size at most  $s$  and let  $T$  be a such a DT of minimum size. Because of Observation 33,  
 1188  $\text{feat}(T)$  is a support set for  $E$  and therefore  $\text{feat}(T)$  contains a minimal support set  $S$  of size  
 1189 at most  $s$ . Because the for-loop in Line 4 of Algorithm 4 iterates over all minimal support  
 1190 sets of size at most  $s$  for  $E$ , it follows that Algorithm 5 is called with parameters  $E$ ,  $s$ , and  
 1191  $S$ . If  $\text{feat}(T) = S$ , then  $B$  is set to a DT for  $E$  of size  $|T|$  in Line 2 of Algorithm 5 and the  
 1192 algorithm will output a DT of size at most  $|T|$  for  $E$ . If, on the other hand,  $\text{feat}(T) \setminus S \neq \emptyset$ ,  
 1193 then because  $T$  has minimum size and  $S$  is a support set for  $E$  with  $S \subseteq \text{feat}(T)$ , we obtain  
 1194 from Lemma 32 that the set  $R = \text{feat}(T) \setminus S$  is useful for  $S$ . Therefore, because of Lemma 30,  
 1195  $R$  has to contain a feature  $f$  from the set  $R_0$  computed in Line 3. It follows that Algorithm 5  
 1196 is called with parameters  $E$ ,  $s$ , and  $S \cup \{v\}$ . From now onwards the argument repeats and

1197 since  $R_0 \neq \emptyset$  the process stops after at most  $s - |S|$  recursive calls after which a DT for  $E$  of  
 1198 size at most  $|T|$  will be computed in Line 2 of Algorithm 5. Finally, it is easy to see that if  
 1199 Algorithm 4 outputs a DT  $T$ , then it is a valid solution. This is because,  $T$  must have been  
 1200 computed in Line 2 of Algorithm 5, which implies that  $T$  is a DT for  $E$ . Moreover,  $T$  has  
 1201 size at most  $s$ , because of Line 8 in Algorithm 4.

1202 To analyse the run-time of the algorithm, we first remark that the whole algorithm can  
 1203 be seen as a bounded-depth search tree algorithm, i.e., a branching algorithm with small  
 1204 recursion depth and few branches at every node. In particular, every recursive call adds at  
 1205 least one feature to the set of features bounding the recursion depth to at most  $s$ . Moreover,  
 1206 every feature that is added is either added in Line 2 of Algorithm 4, when enumerating  
 1207 all minimal support sets, in which case there are at most  $\delta_{\max}(E)$  branches or the feature  
 1208 is added in Line 5 of Algorithm 5, in which case there are at most  $|R_0| \leq s^{2s+3}\delta_{\max}(E)$   
 1209 branches. It follows that the algorithm can be seen as a branching algorithm of depth  
 1210 at most  $s$  with at most  $s^{2s+3}\delta_{\max}(E) = \max\{s^{2s+3}\delta_{\max}(E), \delta_{\max}(E)\}$  branches at every  
 1211 step. Therefore, the total run-time of the algorithm is at most the number of nodes in  
 1212 the branching tree, i.e., at most  $(s^{2s+3}\delta_{\max}(E))^s$ , times the maximum time required in  
 1213 one recursive call. Now the maximum time required for one recursive call is dominated  
 1214 by the time spend in Line 2 of Algorithm 5, i.e., the time required to compute a DT of  
 1215 minimum size using exactly the features in  $S$  with the help of Theorem 34, which is at  
 1216 most  $2^{\mathcal{O}(s^2)}\|E\|^{1+o(1)}\log\|E\|$ . Therefore, we obtain  $(s^{2s+3}\delta_{\max}(E))^s 2^{\mathcal{O}(s^2)}\|E\|^{1+o(1)}\log\|E\|$   
 1217 as the total run-time of the algorithm, which shows that DTS is fixed-parameter tractable  
 1218 parameterized by  $s + \delta_{\max}(E)$ .  $\blacktriangleleft$

#### Algorithm 4 Main method for finding a DT of minimum size.

---

**Input:** CI  $E$  and integer  $s$   
**Output:** DT for  $E$  of minimum size (among all DTs of size at most  $s$ ) if such a DT exists, otherwise  
 nil

```

1: function minDT( $E, s$ )
2:    $\mathcal{S} \leftarrow$  "set of all minimal support sets for  $E$  of size at most  $s$  using Lemma 31"
3:    $B \leftarrow$  nil
4:   for  $S \in \mathcal{S}$  do
5:      $T \leftarrow$  MINDTS( $E, s, S$ )
6:     if ( $T \neq$  nil) and ( $B =$  nil or  $|B| > |T|$ ) then
7:        $B \leftarrow T$ 
8:     if  $B \neq$  nil and  $|B| \leq s$  then
9:       return  $B$ 
10:  return nil

```

---

## 1219 5 Conclusion

1220 We have initiated the study of the parameterized complexity of learning DTs from data. Our  
 1221 main tractability result provides novel insights into the structure of DTs and is based on  
 1222 the NLC-width parameter that seems to be well suited to measure the complexity of input  
 1223 instances for the problem.

1224 The problem of learning DTs comes in many variants and flavors, which opens up a wide  
 1225 range of new research directions to explore. For instance:

- 1226 ■ What other (structural) parameters can be exploited to efficiently learn DTs? Is learning  
 1227 DTs of small size fixed-parameter tractable parameterized by the rank-width of  $G_I(E)$ ?

■ **Algorithm 5** Method for finding a DT of minimum size using at least the features in a given support set  $S$ .

---

**Input:** CI  $E$ , integer  $s$ , support set  $S$  for  $E$  with  $|S| \leq s$

**Output:** DT of minimum size among all DTs  $T$  for  $E$  of size at most  $s$  such that  $S \subseteq \text{feat}(T)$ ; if no such DT exists, **nil**

```

1: function minDTS( $E, s, S$ )
2:    $B \leftarrow$  “compute a DT of minimum size for  $E$  using exactly the features in  $S$  using Theorem ??”
3:    $R_0 \leftarrow$  “compute the branching set  $R_0$  for  $S$  using Lemma 30”
4:   for  $f \in R_0$  do
5:      $T \leftarrow$  MINDTS( $E, s, S \cup \{f\}$ )
6:     if  $T \neq \text{nil}$  and  $|T| < |B|$  then
7:        $B \leftarrow T$ 
8:     if  $|B| \leq s$  then
9:       return  $B$ 
10:    return nil

```

---

- 1228 ■ Instead of learning DTs of small size, one often wants to learn DTs of small height.
- 1229 Therefore, it is natural to ask whether our approach can be also used in this setting.
- 1230 While one can adapt our approach to obtain an XP-algorithm for learning DTs of small
- 1231 height parameterized by NLC-width, it is not clear to us whether the problem also allows
- 1232 for an fpt-algorithm.
- 1233 ■ Can we extend our approach to CIs, where features range over an arbitrary domain? In
- 1234 this case, one usually still uses DTs that make binary decisions (i.e. whether a feature is
- 1235 smaller equal or larger than a given threshold). While it is relatively easy to see that our
- 1236 approach can be extended if the domain’s size (for every feature) is bounded or used as
- 1237 an additional parameter, it is not clear what happens if the size of the domain is allowed
- 1238 to grow arbitrarily.
